COMPREHENSIVE MEDICAL REFERENCE & REVIEW
FOR MCCQE AND USMLE II

Editors-in-Chief: Sara Mirali & Ayesh Seneviratne
Production Managers: Megan Drupals & Matthaeus Ware
Comprehensive medical reference and review for the Medical Council of Canada Qualifying Exam (MCCQE) Part I and the United States Medical Licensing Exam (USMLE) Step II

36th Edition

Editors-in-Chief:
Sara Mirali and Ayesh Seneviratne

Wherever the art of medicine is loved, there is also a love of humanity.

– Hippocrates
Dedicated to all
past and present contributors
and
supporters of Toronto Notes
who have made the production of the 2020 edition possible!

The Toronto Notes for Medical Students is dedicated to helping fund many charitable endeavours and medical student initiatives at the University of Toronto’s Faculty of Medicine and beyond. Programs that have received Toronto Notes for Medical Students funding include:

Community Affairs Projects
• Saturday Program for Inner City High School and Grade 8 students
• St. Felix Mentorship Program for Inner City children
• Parkdale Mentorship Program for Grade 10-12 students
• WoodGreen Community Centre
• Let’s Talk Science
• Growing Up Healthy

Annual Faculty Showcase Events
• Daffydil, in support of the Canadian Cancer Society
• Earthtones Benefit Concert
• Convocation and Ceremonies

Scholarships and Bursaries
• Nishant Fordar Memorial Award
• Graduating Medical Class Scholarships and Bursaries

Medical School Clubs
• Books with Wings
• Women in Medicine
• University of Toronto International Health Program
• Complementary and Alternative Medicine
• Peer Support for Students
• History of Medicine Society
• Faculty of Medicine Yearbook

Other Events
• Save a Child’s Heart
• Australian Medical School Association Conference
• Medical Student Research Day
• Ontario Medical Students Weekend (OMSW)
• OMSA’s Medical Student Education Research Grant (MSERG)

NOTE:
Many of you have wondered about the Toronto Notes logo, which is based on the rod of Asclepius, the Greek god of medicine. The rod of Asclepius consists of a single serpent entwined around a staff. This icon symbolizes both rebirth, by way of a snake shedding its skin, and also authority, by way of the staff.

In ancient Greek mythology, Asclepius was the son of Apollo and a skilled practitioner of medicine who learned the medical arts from the centaur Chiron. Asclepius’ healing abilities were so great that he was said to be able to bring back people from the dead. These powers displeased the gods, who punished Asclepius by placing him in the sky as the constellation Orphichus.

The rod of Asclepius is at times confused with the caduceus, or wand, of Hermes, a staff entwined with two serpents and often depicted with wings. The caduceus is often used as a symbol of medicine or medical professionals, but there is little historical basis for this symbolism.

As you may have guessed, our logo uses the rod of Asclepius that is modified to also resemble the CN Tower – our way of recognizing the university and community in which we have been privileged to learn the art and science of medicine.

Thomas O’Brien, MD
Class of 2009, M.D. Program, University of Toronto
Dear Readers,

As the Editors-in-Chief of Toronto Notes 2020, we are proud to present this updated edition.

Toronto Notes began humbly in 1985 from a set of student notes circulated among medical students at the University of Toronto. Over time, Toronto Notes has grown into one of the premier study resources for generations of medical trainees. This rich history solidified our commitment to publish a comprehensive study resource for medical students engaged in clinical rotations and studying for both the Canadian MCCQE Part 1 and the USMLE Step 2.

For the past 36 years, we have remained committed to our original vision. The 2020 edition of Toronto Notes contains significant improvements including:

1. For the first time, Toronto Notes is offered as a 3 book set. We hope this makes our premier study resource more portable for our readers.
3. The clinical handbook is now combined with STAT notes, making it the perfect resource for all of your clinical rotations. The updated handbook also contains a new quick-reference pharmacology table that provides a succinct overview of common drugs, routes of administration, and usage information.
4. Our updated website has been redesigned to complement your studies. Visit us online for our newly updated Colour Atlas, our Radiology Imaging Database, practice review questions, and more.

We want to highlight the exceptional work of our team, composed of over 150 medical students, medical illustrators, and faculty members at the University of Toronto Faculty of Medicine. Without the tireless effort expended by these individuals, the production of Toronto Notes 2020 would not have been possible. In particular, we would like to highlight the amazing work of our executive team, all of whom made personal sacrifices in balancing their clinical and academic duties with the responsibilities asked of them: our production managers, Megan Drupals and Matthaeus Ware, our associate editors, Vanessa Sheng, Jia Tanwani, Calvin Diep, Jagan Sivakumaran, Danielle Jeong, and Nivethan Vela, our EBM editors, Melissa Allwood, Milica Milakovic, Michael Elfassy, Kimia Sheikholeslami, Khizar Karim, and Ryan Wang, our clinical handbook editors, Priya Dhir, Helen Genis, and Meghan Kerr, and our communication managers, Courtney Francis and Shane Natalwalla. Lastly, we would like to thank our partners at Type & Graphics Inc., particularly Enrica Aguilera, for their assistance during the production of Toronto Notes 2020.

We hope that Toronto Notes 2020 enhances your medical knowledge and allows you to perform better on both your clinical rotations and licensing exams. On behalf of the Toronto Notes 2020 team, we wish you success in your studies and academic endeavours.

Sincerely,

Sara Mirali, BSc (Hons), MD/PhD Candidate and Ayesh Seneviratne, MSc, MD/PhD Candidate
Editors-in-Chief, Toronto Notes 2020
MD Program, University of Toronto

Toronto Notes 2020 is produced by Toronto Notes for Medical Students Inc., which is a non-profit organization supporting various charity organizations in Toronto and beyond. This year, Toronto Notes for Medical Students has supported organizations including medical school clubs, community outreach groups, student bursaries and scholarships, and the Canadian Cancer Society. We would like to thank you for supporting these initiatives through your purchase of Toronto Notes 2020.
Acknowledgements

We would like to acknowledge the exceptional work of all previous Toronto Notes (formerly MCCQE Notes) Editors-in-Chief and their editorial teams. The 36th edition of this text was made possible with their contributions.

How to Use This Book

This book has been designed to remain as one book or to be taken apart into smaller booklets. Identify the beginning and end of a particular section, then carefully bend the pages along the perforated line next to the spine of the book. Then tear the pages out along the perforation.

The layout of Toronto Notes allows easy identification of important information. These items are indicated by icons interspersed throughout the text:

<table>
<thead>
<tr>
<th>Icon</th>
<th>Icon Name</th>
<th>Significance</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image1.png" alt="Icon" /></td>
<td>Key Objectives</td>
<td>This icon is found next to headings in the text. It identifies key objectives and conditions as determined by the Medical Council of Canada or the National Board of Medical Examiners in the USA. If it appears beside a dark title bar, all subsequent subheadings should be considered key topics.</td>
</tr>
<tr>
<td><img src="image2.png" alt="Icon" /></td>
<td>Clinical Pearl</td>
<td>This icon is found in sidebars of the text. It identifies concise, important information which will aid in the diagnosis or management of conditions discussed in the accompanying text.</td>
</tr>
<tr>
<td><img src="image3.png" alt="Icon" /></td>
<td>Memory Aid</td>
<td>This icon is found in sidebars of the text. It identifies helpful mnemonic devices and other memory aids.</td>
</tr>
<tr>
<td><img src="image4.png" alt="Icon" /></td>
<td>Clinical Flag</td>
<td>This icon is found in sidebars of the text. It indicates information or findings that require urgent management or specialist referral.</td>
</tr>
<tr>
<td><img src="image5.png" alt="Icon" /></td>
<td>Evidence Based Medicine</td>
<td>This icon is found in sidebars of the text. It identifies key research studies for evidence-based clinical decision making related to topics discussed in the accompanying text.</td>
</tr>
<tr>

Chapter Divisions
To aid in studying and finding relevant material quickly, each chapter is organized in the following general framework:

Basic Anatomy/Physiology Review
- features the high-yield, salient background information students are often assumed to have remembered from their early medical school education

Common Differential Diagnoses
- aims to outline a clinically useful framework to tackle the common presentations and problems faced in the area of expertise

Diagnoses
- the bulk of the book
- etiology, epidemiology, pathophysiology, clinical features, investigations, management, complications, and prognosis

Common Medications
- a quick reference section for review of medications commonly prescribed

| Prolactin            | <20 ng/mL          | <20 ng/mL      |
| Testosterone (male, free) | 9-30 ng/dL | 0.31-1 pmol/L |
| Thyroxine (T₄)       | 5-12 ng/dL         | 64-155 nmol/L  |
| Triiodothyronine (T₃) | 115-190 ng/dL      | 1.8-2.9 nmol/L |
| TSH                   | 0.5-5 μU/mL        | 0.5-5 μU/mL    |

| **Hematologic Values** |                    |                |
| ESR (female)          | 0-20 mm/h          | 0-20 mm/h      |
| ESR (male)            | 0-15 mm/h          | 0-15 mm/h      |
| Hemoglobin (female)   | 12.3-15.7 g/dL     | 123-157 g/L    |
| Hemoglobin (male)     | 13.5-17.5 g/dL     | 140-174 g/L    |
| Hematocrit (female)   | 36-46%             | 36-46%         |
| Hematocrit (male)     | 41-53%             | 41-53%         |
| INR                   | 1.0-1.1            | 1.0-1.1        |
| Leukocytes            | 4.5-11 x 10³ cells/mm³ | 4.5-11 x 10⁸ cells/L |
| MCV                   | 88-100 μm³         | 88-100 fl      |
| Platelets             | 150-400 x 10³/mm³  | 150-400 x 10⁹/L |
| PTT                   | 25-35 s            | 25-35 s        |
| Reticulocytes         | 0.5-1.5% of RBC    | 20-84 x 10⁹/L  |
Further information on these topics can be found in the Objectives of the Considerations of the Legal, Ethical and Organizational Aspects of the Practice of Medicine (CLEO) – which can be downloaded free of charge from the Medical Council of Canada website at http://mcc.ca/wp-content/uploads/CLEO.pdf.

There are three main types of law in Canada: criminal, civil, and administrative. The penalties for violating each are, in general, as follows: criminal - fine or incarceration; civil - monetary damages paid to the wronged party; and administrative - sanctions by the regulator (such as a suspension by the College of Physicians and Surgeons). All three types of law can be engaged by a single act. For example, a physician that inappropriately touches a patient can be liable for criminal (sexual assault), civil (monetary damages paid to the patient for the civil wrong of sexual assault), and administrative (fines and sanctions up to and including loss of ability to practice medicine for sexual abuse) penalties.

Canadian law applicable to medical practice varies between jurisdictions and changes over time.

Criminal law is nationwide, but civil and administrative law varies between provinces and territories. This section is meant to serve only as a guide. Students and physicians should ensure that their practices conform to local and current laws.
The Canadian Health Care System

- one federal, three territorial, and ten provincial systems
- major complexities in establishment of Canadian health policy include geographical diversity, socioeconomic divisions, and international pressures
- financed by both the public (70%) and private (30%) sectors
- each provincial plan must cover all medically necessary health services delivered in hospitals and by physicians; may choose to cover services such as home care and prescription drugs
- non-insured health services and fees are either covered by private insurance or by the individual
- workers’ compensation funds cover treatment for work-related injuries and diseases

Legal Foundation

The legal foundation of the Canadian health system is based on:

- two constitutional documents:
  1. *Constitution Act* (1867): deals primarily with the jurisdictional power between federal and provincial governments
  2. *The Canadian Charter of Rights and Freedoms* (1982): does not guarantee a right to health care, but given government’s decision to finance health care, they are constitutionally obliged to do so consistently with the rights and freedoms outlined in the Charter (including the right to equality, physicians’ mobility rights, etc.)

- two statutes:
  1. *Canada Health Act* (1984): outlines the national terms and conditions that provincial health systems must meet in order to receive federal transfer payments
  2. *Canada Health and Social Transfer Act* (1996): federal government gives provinces a single grant for health care, social programs, and post-secondary education; division of resources at provinces’ discretion
History of the Canadian Health Care System

1867  *British North America Act (now Constitution Act)* establishes Canada as a confederacy
• “establishment, maintenance, and management of hospitals” under provincial jurisdiction

1965  *Royal Commission on Health Services* (Hall Commission) recommends federal leadership and financial support with provincial government operation

1984  *Canada Health Act* passed by federal government
• replaces *Medical Care Act* (1966) and *Hospital Insurance and Diagnostic Services Act* (1957)
• provides federal funds to provinces with universal hospital insurance
• maintains federal government contribution at 50% on average, with poorer provinces receiving more funds
• medical insurance must be “comprehensive, portable, universal, and publicly administered”
• bans extra-billing by new fifth criterion: accessibility

1996  *Canada Health and Social Transfer Act* passed by federal government
• federal government gives provinces a single grant for health care, social programs, and post-secondary education; division of resources at provinces’ discretion

2001  *Kirby and Romanow Commissions* appointed
- *Kirby Commission* (final report, October 2002)
  • examines history of health care system in Canada, pressures and constraints of current health care system, role of federal government, and health care systems in foreign jurisdictions
  • dialogue with Canadians on the future of Canada’s public health care system

2004  *First Ministers’ Meeting on the Future of Health Care* produces a 10 year plan
• priorities include reductions in waiting times, development of a national pharmacare plan, and primary care reform

2005  *Chaoulli v. Québec*, Supreme Court of Canada decision
• rules that Québec’s banning of private insurance is unconstitutional under the Québec Charter of Rights, given that patients do not have access to those services under the public system in a timely way

2011  First progress report by the Health Council reviews progress (2004 First Ministers’ 10 year plan)
• significant reductions in wait times for specific areas (such as cancer, joint replacement, and sight restoration), but may have inadvertently caused increases in wait times of other services
• despite large investments into EMRs, Canada continues to have very low uptake, ranking last in the Commonwealth Fund International Health Policy survey, with only 37% use among primary care physicians
• little progress in creating a national strategy for equitable access to pharmaceuticals; however, there has been some success in increasing pharmacists’ scope of practice, reducing generic drug costs, and implementing drug information systems
• increases in funding to provinces at 6% per annum until the 2016-2017 fiscal year; from then onwards, increases tied to nominal GDP at a minimum of 3% per annum

2012  Second progress report by the Health Council reviews progress towards 2004 First Ministers’ 10 year plan
• funding is sufficient; however, more innovation is needed including incentivizing through models of remuneration
• 46 recommendations made to address the lack of progress

2014  Expiry of current 10 Year Health Care Funding Agreement between federal and provincial governments
• *Canadian Doctors for Refugee Care v. Canada*, the Federal Court of Canada ruled that the federal government could not significantly reduce/eliminate healthcare services for refugee claimants as to do so would constitute “cruel and unusual treatment” contrary to the Charter of Rights and Freedoms

2015  Negotiations underway for a new Health Accord with a $3 billion investment over four years to homecare and mental health services by the elected Liberal government

2017  New 10 year Canada Health Accord reached with a $11.5 billion federal investment over 10 years to homecare and mental health services and a 3% annual rise in the Canada Health Transfer (down from 6% in the previous agreement) by the elected Liberal government

2019  The federal government announced the creation of a national drug agency. It will negotiate prices on behalf of Canada’s drug plans, assess the effectiveness of prescription drugs, and develop a national formulary
Health Care Expenditure and Delivery in Canada

- The projected total health care expenditure in 2018 is expected to reach $253.5 billion, comprising 11.3% of the GDP, or approximately $6839 CDN per person.

Sources of Health Care Funding

- 69% of total health expenditure in 2018 came from public-sector funding with 65% coming from the provincial and territorial governments, and another 5% from other parts of the public sector: federal direct government, municipal, and social security funds. 31% is from private sources including out of pocket (16%), private insurance (12%), and other (3%).
- Public sector covers services offered on either a fee for service, capitation, or alternate payment plan in physicians' offices and in hospitals.
- Public sector does not cover services provided by privately practicing health professionals (e.g. dentists, chiropractors, optometrists, massage therapists, osteopaths, physiotherapists, podiatrists, psychologists, private duty nurses, and naturopaths), prescription drugs, OTC drugs, personal health supplies, and use of residential care facilities.

Figure 1. Total health expenditure per capita by use of funds, Canada 2018 (dollars and percentage share)

Adapted from source: National Health Expenditure Database, Canadian Institute for Health Information

Delivery of Health Care

- Hospital services in Canada are publicly funded but delivered through private, not-for-profit institutions owned and operated by communities, religious organizations, and regional health authorities.
- Other countries, such as the United States (a mix of public and private funding, as well as private for-profit and private not-for-profit delivery), and the United Kingdom (primarily public funding and delivery) have different systems of delivery.

Physician Licensure and Certification

Table 2. Key Physician Certification and Licensing Bodies in Canada

<table>
<thead>
<tr>
<th>Certification Body</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MCC</td>
<td>Certifies physicians with the LMCC. LMCC acquired by passing the MCC Qualifying Examination Parts I and II</td>
</tr>
<tr>
<td>RCPSC</td>
<td>Certifies specialists who complete an accredited residency program and pass the appropriate exam. Voluntary membership of the RCPSC is designated FRCPC or FRCSC</td>
</tr>
<tr>
<td>CFPC</td>
<td>Certifies family physicians who complete an accredited residency program and pass the Certification Examination in Family Medicine</td>
</tr>
<tr>
<td>CPSO</td>
<td>13 provincial medical regulatory (licensing) authorities. All postgraduate residents and all practicing physicians must hold an educational or practice license from the licensing body in the province in which they study or practice. Membership to the provincial licensing authority is mandatory. Licensing authority functions include: Provide non-transferable licence to physicians Maintaining ethical, legal, and competency standards and developing policies to guide doctors Investigating complaints against doctors Disciplining doctors guilty of professional misconduct or incompetence. At times of license investiture and renewal, physicians must disclose if they have a condition (such as HIV positivity, drug addiction, or other illnesses) that may impact their ability to practice safely.</td>
</tr>
</tbody>
</table>
• physician certification is governed nationally, while the medical profession in Canada self-regulates under the authority of provincial legislation
• self-regulation is based on the premise that due to the advanced education and training involved in the practice of medicine, the lay person is not in a position to accurately judge the standards of the profession; the self-regulating colleges have a mandate to regulate the profession in the public interest
• the RCPSC and CFPC are responsible for monitoring ongoing CME and professional development
• certification by the LMCC plus either the RCPSC or CFPC is a minimum requirement for licensure by most provincial licensing authorities

Role of Professional Associations

Table 3. Key Professional Associations

</tbody>
</table>

Ethical and Legal Issues in Canadian Medicine

Introduction to the Principles of Ethics

• ethics addresses:
  1. principles and values that help define what is morally permissible or not
  2. rights, duties, and obligations of individuals and groups
• the practice of medicine assumes there is one code of professional ethics for all doctors and that they will be held accountable by that code and its implications
• the doctor-patient relationship is formed on trust, which is recognized in the concept of fiduciary duty/responsibility of physician towards patient
• a fiduciary duty is a legal duty to act in another party’s interest. Profit from the fiduciary relationship must be strictly accounted for with any improper profit (monetary or otherwise) resulting in sanctions against the physician and potentially compensation to the patient, even if no harm has befallen the patient

Table 4. The Four Principles Approach to Medical Ethics

<table>
<thead>
<tr>
<th>Principle</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Autonomy</td>
<td>Recognizes an individual’s right and ability to decide for themselves according to their beliefs and values May not be applicable in situations where informed consent and choice are not possible or may not be appropriate</td>
</tr>
<tr>
<td>Beneficence</td>
<td>Patient values-based best interests standard that combines doing good, avoiding harm, considering the patient's values, beliefs, and preferences, so far as these are known Autonomy should be integrated with the physician’s conception of a patient’s medically-defined best interests Aim is to minimize harmful outcomes and maximize beneficial ones Paramount in situations where consent/choice is not possible or may not be appropriate</td>
</tr>
<tr>
<td>Non-Maleficence</td>
<td>Obligation to avoid causing harm; primum non nocere (“First, do no harm”) Limit condition of the Beneficence principle</td>
</tr>
<tr>
<td>Justice</td>
<td>Fair distribution of benefits and harms within a community, regardless of geography or income Concept of fairness: Is the patient receiving what they deserve – their fair share? Are they treated the same as equally situated patients? (equality) How does one set of treatment decisions impact others? (equity) Equality and equity are different notions of justice. Equality is distribution of resources to all irrespective of needs, and equity is distribution of resources based on unique needs. Both concepts raise different considerations Basic human rights, such as freedom from persecution and the right to have one’s interests considered and respected</td>
</tr>
</tbody>
</table>
CMA Code of Ethics
- the CMA developed a Code of Ethics that acts as a common ethical framework for Canadian physicians
- the Code of Ethics is:
  - prepared by physicians for physicians and applies to physicians, residents, and medical students
  - based on the fundamental ethical principles of medicine
  - sources include the Hippocratic Oath, developments in human rights, recent bioethical discussion
  - CMA policy statements address specific ethical issues not mentioned by the code (e.g. abortion, transplantation, and euthanasia)

Overview of Confidentiality
- when determining legal and ethical issues surrounding patient information, start from the point that all information given by the patient is both confidential (meaning it cannot be disclosed to others) and privileged (meaning it cannot be used in court), then determine whether exceptions to this exist
- the legal and ethical basis for maintaining confidentiality is that a full and open exchange of information between patient and physician is central to a therapeutic relationship
- privacy is the right of patients (which they may forego), while confidentiality is the duty of doctors (which they must respect barring patient consent or the requirements of the law)
- if improperly breached by a doctor, physician can be sanctioned by the hospital, court, or regulatory authority
- based on the ethical principle of patient autonomy, patients have the right to the following:
  - control of their own information
  - the expectation that information concerning them will receive proper protection from unauthorized access by others (see Privacy of Medical Records, ELOM7)
- confidentiality may be ethically and legally breached in certain circumstances (e.g. the threat of harm to others)
  - while physician-patient privilege exists, it is less strong than solicitor-client privilege. Physicians can tell patients that they will only disclose their information where it is mandated by law and that these exceptions are generally quite narrow. Physicians should avoid promising absolute confidentiality or privilege, as it cannot be guaranteed
- physicians should seek advice from their local health authority or the CMPA before disclosing HIV status of a patient to someone else
  - many jurisdictions make mandatory not only the reporting of serious communicable diseases (e.g. HIV), but also the reporting of those who harbour the agent of the communicable disease
  - physicians failing to abide by such regulations could be subject to professional or civil actions
- legal duty to maintain patient confidentiality is imposed by provincial health information legislation and precedent-setting cases in the common law

Statutory Reporting Obligations
- legislation has defined specific instances where public interest overrides the patient's right to confidentiality; varies by province, but may include:
  1. suspected child abuse or neglect – report to local child welfare authorities (e.g. Children's Aid Society)
  2. fitness to drive a vehicle or fly an airplane – report to provincial Ministry of Transportation (see Geriatric Medicine, GM11)
  3. communicable diseases – report to local public health authority (see Public Health and Preventive Medicine, PH26)
  4. improper conduct of other physicians or health professionals – report to College or regulatory body of the health professional (sexual impropriety by physicians is required reporting in some provinces)
  5. vital statistics must be reported; reporting varies by province (e.g. in Ontario, births are required to be reported within 30 d to Office of Registrar General or local municipality; death certificates must be completed by a MD then forwarded to municipal authorities)
  6. reporting to coroners (see Physician Responsibilities Regarding Death, ELOM16)
- physicians who fail to report in these situations are subject to prosecution and penalty, and may be liable if a third party has been harmed

Duty to Protect/Warn
- the physician has a duty to protect the public from a known dangerous patient; this may involve taking appropriate clinical action (e.g. involuntary detainment of violent patients for clinical assessment), informing the police, or warning the potential victim(s) if a patient expresses an intent to harm
- first established by a Supreme Court of California decision in 1976 (Tarasoff v. Regents of the University of California)
- Canadian courts have not expressly imposed a mandatory duty to report, however, the CMA Code of Ethics and some provincial/territorial regulatory authorities may oblige physicians to report (mandatory reporting rather than permissive)
- concerns of breaching confidentiality should not prevent the MD from exercising the duty to protect; however, the disclosed information should not exceed that required to protect others...
• applies in a situation where:
  1. there is an imminent risk
  2. to an identifiable person or group
  3. of serious bodily harm or death

Disclosure for Legal Proceedings
• disclosure of health records can be compelled by a court order, warrant, or subpoena

Privacy of Medical Records
• privacy of health information is protected by professional codes of ethics, provincial and federal legislation, the Canadian Charter of Rights and Freedoms, and the physician's fiduciary duty
• the federal government created the PIPEDA in 2000 which established principles for the collection, use, and disclosure of information that is part of commercial activity (e.g. physician practices, pharmacies, private labs)
• PIPEDA has been superseded by provincial legislation in many provinces, such as the Ontario Personal Health Information Protection Act, which applies more specifically to health information

Duties of Physicians with Regard to the Privacy of Health Information
• inform patients of information-handling practices through various means (e.g. posting notices, brochures and pamphlets, and/or through discussions with patients)
• obtain the patient's expressed consent to disclose information to third parties
  • under Ontario privacy legislation, the patient's expressed consent need not be obtained to share information between health care team members involved in the “circle of care.” However, the patient may withdraw consent for this sharing of information and may parts of the chart in a “lock box”
  • physicians have a professional obligation to facilitate timely transmission of the patient's medical record to third parties (with the patient's consent), such as for insurance claims. Failure to do so has resulted in sanctions by regulatory bodies
  • while patients have a right of access to their medical records, physicians can charge a “reasonable fee” commensurate with the time and material used in providing copies/access
• provide the patient with access to their entire medical record; exceptions include instances where there is potential for serious harm to the patient or a third party
• provide secure storage of information and implement measures to limit access to patient records
• ensure proper destruction of information that is no longer necessary
• regarding taking pictures or videos of patients, findings, or procedures, in addition to patient consent and privacy laws, trespassing laws apply in some provinces
• CPSO published policy is designed to help Ontario physicians understand legal and professional obligations set out under the Regulated Health Professions Act, 1991, the Medicine Act, 1991, and the Personal Health Information Protection Act, 2004. This includes regulations regarding express or implied consent, incapacity, lock boxes, disclosure under exceptional circumstances, mandatory reporting, ministry audits, subpoenas, court orders and police, and as well as electronic records and voice messaging communications: http://www.cpso.on.ca/Policies-Publications/Policy/Confidentiality-of-Personal-Health-Information
• it is the physician's responsibility to ensure appropriate security provisions with respect to electronic records and communications
  • with the advent of digital records, there have been increasing issues with access of healthcare providers that are not part of the patient's circle of care accessing medical records inappropriately (e.g. curiosity or for profit). All staff should be aware that most EMRs log which healthcare providers view records and automatically flag files for further review in certain cases (e.g. same surname, VIP patients, audit of access to records)

Consent and Capacity

Ethical Principles Underlying Consent and Capacity
• consent is the autonomous authorization of a medical intervention by a patient
• usually the principle of respect for patient autonomy must be balanced by the principle of beneficence
• where a patient cannot make an autonomous decision (i.e. incapable), it is the duty of the SDM (or the physician in an emergency) to act on the patient's known prior wishes or, failing that, to act in the patient's best interests
• there is a duty to discover, if possible, what the patient would have wanted when capable
• central to determining best interests is understanding the patient's values, beliefs, and patient's interpretation of cultural or religious background
• more recently expressed wishes take priority over remote ones
• patient wishes may be verbal or written
• patients found incapable to make a specific decision should still be involved in that decision as much as possible; this is known as assent
• agreement or disagreement with medical advice does not determine findings of capacity/incapacity
• however, patients opting for care that puts them at risk of serious harm that most people would want to avoid should have their capacity carefully assessed. Steer clear from tendency to define what reasonable person standard may be. If appropriate, look to discern patterns of justification offered by patient and how they interpret their values, beliefs and culture/religion
Four Basic Requirements of Valid Consent

1. Voluntary
   - consent must be given free of coercion or pressure (e.g. from parents or other family members who might exert ‘undue influence’)
   - the physician must not deliberately mislead the patient about the proposed treatment

2. Capable
   - the patient must be able to understand and appreciate the nature and effect of their condition as well as of the proposed treatment or decision

3. Specific
   - the consent provided is specific to the procedure being proposed and to the provider who will carry out the procedure (e.g. the patient must be informed if students will be involved in providing the treatment)

4. Informed
   - sufficient information and time must be provided to allow the patient to make choices in accordance with their wishes, including:
     - the nature of the treatment or investigation proposed and its expected effects
     - all significant risks and special or unusual risks
     - alternative treatments or investigations and their anticipated effects and significant risks
     - the consequences of declining treatment
     - answers to any questions the patient may have
     - the reasonable person test – the physician must provide all information that would be needed “by a reasonable person in the patient’s position” to be able to make a decision
     - disclose common adverse events and all serious risks (e.g. death), even if remote
     - it is the physician’s responsibility to make reasonable attempts to ensure that the patient understands the information, including overcoming language barriers, or communication challenges
     - physicians have a duty to inform the patient of all legitimate therapeutic options and must not withhold information based on conscientious objections (e.g. not discussing the option of emergency contraception)

---

Is this a “treatment”?  

Yes  Yes

No  Yes  No

Use common law

Is this an emergency?  

Yes

No

Discuss involvement of SDM

Does patient dispute the finding of incapacity

Yes

Review Board

Incapacity

No

Does the SDM consent?

Yes

No

Do not treat

Treat

Does the patient consent?

Yes

No

If there is no SDM for the incapable patient, the doctor can apply to the CCB to appoint a patient representative

If the doctor has good reason to think the SDM is making inappropriate decisions for the incapable patient, an application can be made to the CCB to review the SDM’s decisions and appoint a new patient representative

---

Professional Considerations

- Elderly Patient
  - Identify their goals of care and resuscitation options (CPR or DNR), if applicable
  - Check for documentation of advance directives and POA where applicable

- Pediatric Patient
  - Identify the primary decision-maker (parents, guardian, wards-of-state, emancipated)
  - Regarding capacity assessment see Pediatric Aspects of Capacity, ELOM11
  - Be wary of custody issues if applicable

- Emergency or Palliative Patient
  - Consider the SPIKES approach to breaking bad news
  - What are patient’s goals of care (e.g. disease vs. symptom management?)
  - Identify advance directives, POA, or SDM, if applicable (see ELOM10)
  - Check for documentation of resuscitation options (CPR or DNR) and likelihood of success

- Incapable Patient
  - If not already present, perform a formal capacity assessment and thoroughly document
  - Identify if the patient has an SDM or who has their POA
  - Check the patient’s chart for any Mental Health Forms (e.g. Form 1) or any forms they may have on their person (e.g. Form 42)

---

Criteria For Administration of Treatment for an Incapable Patient in Emergency Situations

- Patient is experiencing extreme suffering
- Patient is at risk of sustaining serious bodily harm if treatment is not administered promptly (loss of life or limb)

Patients may also ask to waive the right to choose (e.g. “You know what’s best for me, doctor”) or delegate their right to choose to someone else (e.g. a family member)

This is not necessarily only in emergency situations. Patients may choose to exercise relational autonomy i.e. conception of self-determination where decisions are made considering relationships and person’s social supports. The patient is still in the centre, but chooses to involve others in the decision

---

Toronto Notes 2020
Obtaining Legal Consent
- Consent of the patient must be obtained before any medical intervention is provided; consent can be:
  - verbal or written, although written is usually preferred
  - a signed consent form is only evidence of consent – it does not replace the process for obtaining valid consent
  - most important component is what the patient understands and appreciates, not what the signed consent form states
  - implied (e.g. a patient holding out their arm for an immunization) or expressed
  - consent is an ongoing process and can be withdrawn or changed after it is given, unless stopping a procedure would put the patient at risk of serious harm
- If consent has been withdrawn during a procedure, the MD must stop treatment unless stopping the procedure would threaten the patient’s life
- In obtaining consent to continue the procedure, the physician needs only re-explain the procedure and risks if there has been a material change in circumstances since obtaining consent originally. If there has been no material change in circumstances, simple assent to continue is sufficient (Carlariello v. Schachter)
- HCCA of Ontario (1996) covers consent to treatment, admission to a facility, and personal assistance services (e.g. home care)

Exceptions to Consent
1. Emergencies
- Treatment can be provided without consent where a patient is experiencing severe suffering, or where a delay in treatment would lead to serious harm or death and consent cannot be obtained from the patient or their SDM
- Emergency treatment should not violate a prior expressed wish of the patient (e.g. a signed Jehovah's Witness card)
- If a patient is incapable, MD must document reasons for incapacity and why the situation is emergent
- Patients have a right to challenge a finding of incapacity as it removes their decision-making ability
- If a SDM is not available, MD can treat without consent until the SDM is available or the situation is no longer emergent

2. Legislation
- Mental health legislation allows for:
  - the detention of patients without their consent
  - Psychiatric outpatients may be required to adhere to a care plan in accordance with Community Treatment Orders
  - Public Health legislation allows medical officers of health to detain, examine, and treat patients without their consent (e.g. a patient with TB refusing to take medication) to prevent transmission of communicable diseases

3. Special Situations
- Public health emergencies (e.g. an epidemic or communicable disease treatment)
- Warrant for information by police

Consequences of Failure to Obtain Valid Consent
- Treatment without consent is battery (an offense in tort), even if the treatment is life-saving (excluding situations outlined in Exceptions to Consent)
- Treatment of a patient on the basis of poorly informed consent may constitute negligence, also an offense in tort
- The onus of proof that valid consent was not obtained rests with the plaintiff (usually the patient)

Overview of Capacity
- Capacity is the ability to:
  - Understand information relevant to a treatment decision
  - Appreciate the reasonably foreseeable consequences of a decision or lack of a decision
  - Capacity is specific for each decision (e.g. a person may be capable to consent to having a chest x-ray, but not for a bronchoscopy)
  - Capacity can change over time (e.g. temporary incapacity secondary to delirium)
  - Most Canadian jurisdictions distinguish capacity to make healthcare decisions from capacity to make financial decisions; a patient may be deemed capable of one, but not the other
  - A person is presumed capable unless there is good evidence to the contrary
  - Capable patients are entitled to make their own decisions
  - Capable patients can refuse treatment even if it leads to serious harm or death; however, decisions that put patients at risk of serious harm or death require careful scrutiny

Assessment of Capacity
- Capacity assessments must be conducted by the clinician providing treatment and, if appropriate, in consultation with other healthcare professionals (e.g. another physician, a mental health nurse)
- Clinical capacity assessment may include:
  - Specific capacity assessment (i.e. capacity specific to the decision at hand):
    1. Effective disclosure of information and evaluation of patient's reason for decision
    2. Understanding of:
       - Their condition
       - The nature of the proposed treatment
Treatments of the Incapable Patient in a Non-Emergent Situation

- **obtain informed consent from SDM**
- **an incapable patient can only be detained against their will to receive treatment if they meet criteria for certification under the Mental Health Act (see Psychiatry, PS53); in such a situation:**
  - document assessment in chart
  - notify patient of assessment using appropriate Mental Health Form(s) (Form 42 in Ontario)
  - notify Rights Advisor

**Substitute Decision-Makers**

- SDMs must follow the following principles when giving informed consent:
  - act in accordance with wishes previously expressed by the patient while capable
  - if wishes unknown, act in the patient's best interest, taking the following into account:
    1. values and beliefs held by the patient while capable
    2. whether well-being is likely to improve with vs. without treatment
    3. whether the expected benefit outweighs the risk of harm
    4. whether a less intrusive treatment would be as beneficial as the one proposed
- the final decision of the SDM may and should be challenged by the MD if the MD believes the SDM is not abiding by the above principles

**Instructional Advance Directives**

- allow patients to exert control over their care once they are no longer capable
- the patient sets out their decisions about future health care, including who they would allow to make treatment decisions on their behalf and what types of interventions they would want
- takes effect once the patient is incapable with respect to treatment decisions
- in Ontario, a person can appoint a power of attorney for personal care to carry out their advance directives
  - the legal threshold to appoint a Power of Attorney for personal care is intentionally set lower than the legal threshold for capacity to consent to many complex medical treatments. This allows a patient that lacks treatment capacity to appoint a person of their choosing to make the decision for them
- patients should be encouraged to review these documents with their family and physicians and to reevaluate them often to ensure they are current with their wishes

**POWERS OF ATTORNEY**

- all Guardians and Attorneys have fiduciary duties for the dependent person

**Definitions**

- **Power of Attorney for Personal Care**
  - a legal document in which one person gives another the authority to make personal care decisions (health care, nutrition, shelter, clothing, hygiene, and safety) on their behalf if they become mentally incapable
- **Guardian of the Person**
  - someone who is appointed by the Court to make decisions on behalf of an incapable person in some or all areas of personal care, in the absence of a FOA for personal care
- **Continuing Power of Attorney for Property**
  - legal document in which a person gives another the legal authority to make decisions about their finances if they become unable to make those decisions
- **Guardian of Property**
  - someone who is appointed by the Public Guardian and Trustee or the Courts to look after an incapable person's property or finances
- **Public Guardian and Trustee**
  - acts as a SDM of last resort on behalf of mentally incapable people who do not have another individual to act on their behalf
• **Pediatric Aspects of Capacity Covered**
  - no age of consent in all provinces and territories except Quebec; consent depends on patient's decision-making capacity
  - Quebec has a specific age of consent, but common law and case law deem underage legal minors capable, allowing these individuals to make their own choices
  - infants and children are assumed to lack mature decision-making capacity for consent but they should still be involved (i.e. be provided with information appropriate to their comprehension level)
  - adolescents are usually treated as adults
  - preferably, assent should still be obtained from patient, even if not capable of giving consent
  - in the event that the physician believes the SDM is not acting in the child's best interests, an appeal must be made to the local child welfare authorities
  - under normal circumstances, parents have right of access to the child's medical record

### Ethical Basis

**Negligence**

- the doctor-patient relationship is formed on trust, which is recognized in the concept of fiduciary duty/ responsibility of physician towards patient
- negligence or malpractice is a form of failure on the part of the physician in fulfilling their fiduciary duty in providing appropriate care and leading to harm of the patient (and/or abuse of patient's trust)

**Legal Basis**

- physicians are legally liable to their patients for causing harm (tort) through a failure to meet the standard of care applicable under the circumstances
- standard/duty of care is defined as one that would reasonably be expected under similar circumstances of an ordinary, prudent physician of the same training, experience, specialization, and standing
- liability arises from physician's common law duty of care to their patients in the doctor/patient relationship (or, in Quebec, from the Civil Code provisions regarding general civil liability)
- action(s) in negligence (or civil liability) against a physician must be launched by a patient within a specific prescribed period required by the respective province in which the actions occurred

### Truth-Telling

**Ethical Basis**

- helps to promote and maintain a trusting physician-patient relationship
- patients have a right to be told important information that physicians have regarding their care
- enables patients to make informed decisions about health care and their lives

**Legal Basis**

- required for valid patient consent (see Consent and Capacity, ELOM7)
  - goal is to disclose information that a reasonable person in the patient's position would need in order to make an informed decision ("standard of disclosure")
  - withholding information can be a breach of fiduciary duty and duty of care
  - obtaining consent on the basis of misleading information can be seen as negligent

**Evidence about Truth-Telling**

- it is a patient's right to have the option of knowing what is wrong with them
- most patients want to know what is wrong with them
- although many patients want to protect family members from bad news, they themselves would want to be informed in the same situation
- truth-telling improves adherence and health outcomes
- informed patients are more satisfied with their care and most often take the news better than expected
- negative consequences of truth-telling can include decreased emotional well-being, anxiety, worry, social stigmatization, and loss of insurability

**Challenges in Truth-Telling**

**Medical Error**

- medical error may be defined as ‘preventable adverse events (AEs)’ caused by the patient's medical care and not the patient's underlying illness; some errors may be identified before they harm the patient, so not all error is truly ‘adverse’
- many jurisdictions and professional associations expect and require physicians to disclose medical error; that is, any event that harms or threatens to harm patients must be disclosed to the patient or the patient's family and reported to the appropriate health authorities
- physicians must disclose to patients the occurrence of AEs or errors caused by medical management, but should not suggest that they resulted from negligence because:
  - negligence is a legal determination
  - error is not equal to negligence
• disclosure allows the injured patient to seek appropriate corrective treatment promptly
• physicians should avoid simple attributions as to cause and sole responsibility of others or oneself
• physicians should offer apologies or empathic expressions of regret (e.g. “I wish things had turned out differently”) as these build trust and are not admissions of guilt or liability
• Apology Acts across Canada protect apologies, both as expressions of regret and admissions of responsibility, from being used as evidence of liability and negligence

**Breaking Bad News**
• “bad news” may be any information that reveals conditions or illnesses threatening the patient’s sense of well-being
• poorly done disclosure may be as harmful as non-disclosure
  • caution patients in advance of serious tests and disclose possible bad findings
  • give time for patient to reflect prior to receiving such news
  • give warnings of impending bad news by reviewing prior discussions
  • provide time for the patient and questions
  • adequate supports and strategies should always be provided following disclosure of difficult news
• SPIKES protocol was developed to facilitate “breaking bad news”
  • SETTING and LISTENING SKILL
  • Patient PERCEPTIONS of condition and seriousness
  • INVITATION from patient to receive information
  • KNOWLEDGE - provide medical facts
  • Explore EMOTIONS and EMPATHIZE
  • STRATEGY and SUMMARY

**Arguments Against Truth-Telling**
• may go against certain cultural norms and expectations
• may lead to patient harm, but only in extreme, rare situations
• medical uncertainty may result in the disclosure of uncertain or inaccurate information

**Exceptions to Truth-Telling**
• a patient may waive their right to know the truth about their situation (i.e. decline information that would normally be disclosed) when:
  • the patient clearly declines to be informed
  • a strong cultural component exists that should be respected and acknowledged
  • the patient may wish others to be informed and make the medical decisions for them
  • the more weight for the consequences for the patient from non-disclosure, the more carefully one must consider the right to ignorance
  • ‘emergencies’: an urgent need to treat may legitimately delay full disclosure; the presumption is that most people would want such treatment and the appropriate SDM cannot be found
  • ‘therapeutic privilege’
    • withholding of information by the clinician in the belief that disclosure of the information would itself lead to severe anxiety, psychological distress, or physical harm to the patient
    • clinicians should avoid invoking therapeutic privilege due to its paternalistic overtones; it is a defence of non-disclosure that is rarely accepted anymore
    • it is often not the truth that is unpalatable; it is how it is conveyed that can harm the patient

**Ethical Issues in Health Care**

**Managing Controversial and Ethical Issues in Practice**
• discuss in a non-judgmental manner
• ensure patients have full access to relevant and necessary information
• identify if certain options lie outside the physician’s moral boundaries and refer to another physician if appropriate
• consult with appropriate ethics committees or boards
• protect freedom of moral choice for students or trainees

**Reproductive Technologies**

**Overview of the Maternal-Fetal Relationship**
• in general, maternal and fetal interests align
• in some situations, a conflict between maternal autonomy and the best interests of the fetus may arise

**Ethical Issues and Arguments**
• principle of reproductive freedom: women have the right to make their own reproductive choices
• coercion of a woman to accept efforts to promote fetal well-being is an unacceptable infringement of her personal autonomy
Legal Issues and Arguments
- the law protects a woman’s right to life, liberty, and security of person, and does not recognize fetal rights; key aspects of the mother’s rights include:
  - if a woman is competent and refuses medical advice, her decision must be respected even if the fetus will suffer
  - the fetus does not have legal rights until it is born alive and with complete delivery from the body of the woman
  - a pregnant woman that is addicted to teratogenic substances cannot be detained and treated to protect the fetus (Winnipeg Child and Family Services (Northwest Area) v G. (D.F.), [1997] 3 S.C.R. 925)
  - a fetus is not a “human being” within the meaning of the Criminal Code of Canada, thus medical negligence during delivery resulting in the death of a fetus that has not been born alive does not constitute criminal negligence causing death (manslaughter) and cannot attract criminal penalties (R v Sullivan)

Royal Commission on New Reproductive Technologies (1993) recommendations:
1. medical treatment must never be imposed upon a competent pregnant woman against her wishes
2. no law should be used to confine a pregnant woman in the interest of her fetus
3. the conduct of a pregnant woman in relation to her fetus should not becriminalized
4. child welfare should never be used to control a woman’s behaviour during pregnancy
5. civil liability should never be imposed upon a woman for harm done to her fetus during pregnancy

Examples involving the use of established guidelines
- a woman is permitted to refuse HIV testing during pregnancy, even if vertical transmission to fetus
- a woman is permitted to refuse Caesarean section in labour that is not progressing, despite evidence of fetal distress

Advanced Reproductive Therapies
- includes non-coital insemination, hormonal ovarian stimulation, and IVF
- topics with ethical concerns:
  - donor anonymity vs. child-centred reproduction (i.e. knowledge about genetic medical history)
  - preimplantation genetic testing for diagnosis before pregnancy
  - use of new techniques without patients appreciating their experimental nature
  - embryo status – the Supreme Court of Canada maintains that fetuses are “unique” but not persons under law; this view would likely apply to embryos as well
  - access to ART
  - private vs. public funding of ART
  - social factors limiting access to ART (e.g. same-sex couples)
  - the ‘commercialization’ of reproduction

Fetal Tissue
- pluripotent stem cells can currently be derived from human embryonic and fetal tissue
- potential uses of stem cells in research
  - studying human development and factors that direct cell specialization
  - evaluating drugs for efficacy and safety in human models
  - cell therapy: using stem cells grown in vitro to repair or replace degenerated/destroyed/malignant tissues (e.g. Parkinson’s disease)
  - genetic treatment aimed at altering somatic cells (e.g. myocardial or immunological cells) is acceptable and ongoing

Induced Abortion
- CMA definition of induced abortion: the active termination of a pregnancy before fetal viability (fetus >500 g or >20 wk GA)
- CMA policy on induced abortion
  1. induced abortion should not be used as an alternative to contraception
  2. counselling on contraception must be readily available
  3. full and immediate counselling services must be provided in the event of unwanted pregnancy
  4. there should be no delay in the provision of abortion services
  5. no patient should be compelled to have a pregnancy terminated
  6. physicians should not be compelled to participate in abortion – if morally opposed, the physician should inform the patient so she may consult another physician
  7. no discrimination should be directed towards either physicians who do not perform or assist at induced abortions or physicians who do
  8. induced abortion should be uniformly available to all women in Canada and health care insurance should cover all the costs (note: the upper limit of GA for which coverage is provided varies between provinces)
  9. elective termination of pregnancy after fetal viability may be indicated under exceptional circumstances
Ethical and Legal Concerns and Arguments
- in Canada, there is no criminal prohibition regarding abortion
- it is a woman's medical decision to be made in consultation with whom she wishes; there is no mandatory role for spouse/family
- 2nd and even 3rd trimester abortions are not illegal in Canada, but are usually only carried out when there are serious risks to the woman's health, or if the fetus has died in utero or has major malformations (e.g. anencephaly). Medical termination of pregnancy (MTP) for social reasons are now conducted in select medical centres in Canada

Prenatal/Antenatal Genetic Testing
- uses
  1. to confirm a clinical diagnosis
  2. to detect genetic predisposition to a disease
  3. allows preventative steps to be taken and helps patient prepare for the future
  4. gives parents the option to terminate a pregnancy or begin early treatment
- ethical dilemmas arise because of the sensitive nature of genetic information; important considerations of genetic testing include:
  - the individual and familial implications
  - its pertinence to future disease
  - its ability to identify disorders for which there are no effective treatments or preventive steps
  - its ability to identify the sex of the fetus
- ethical issues and arguments regarding the use of prenatal/antenatal genetic testing include:
  - obtaining informed consent is difficult due to the complexity of genetic information
  - doctor’s duty to maintain confidentiality vs. duty to warn family members
  - risk of social discrimination (e.g. insurance) and psychological harm

Legal Aspects
- no current specific legislation exists
- testing requires informed consent
- no standard of care exists for clinical genetics, but physicians are legally obligated to inform patients that prenatal testing exists and is available
- a physician may be able to breach confidentiality in order to warn family members about a condition if harm can possibly be prevented via treatment or prevention. In general, the patient’s consent is required, unless the harm to be avoided is sufficiently serious to rise to the level of imminent risk of serious bodily harm or death (i.e. not a chronic condition, but an acute life-threatening condition)

Genetic Testing: Ethically Appropriate Actions
- thorough discussion and realistic planning with patient before testing is done
- genetic counselling for delivery of complex information

End-of-Life Care

Overview of Palliative and End-of-Life Care
- focus of care is comfort and respect for person nearing death and maximizing quality of life for patient, family, and loved ones
  - palliative care is an approach that improves the quality of life of patients facing life-threatening illness, through the prevention and relief of suffering, including treating pain, physical, psychosocial, and spiritual concerns
  - appropriate for any patient at any stage of a serious or life-limiting illness
  - may occur in a hospital, hospice, in the community, or at home
  - often involves an interdisciplinary team of caregivers
  - addresses the medical, psychosocial, and spiritual dimensions of care

Euthanasia and Medical-Assistance in Dying (MAID)
- euthanasia: knowingly and intentionally performing an act, with or without consent, that is explicitly intended to end another person’s life where that person has an incurable illness
- medical-assistance in dying: the administering or prescribing for self-administration, by a medical practitioner or nurse practitioner, of a substance, at the request of a person, that causes their death
  - palliative sedation: the use of sedative medications for patients that are terminally ill to relieve suffering and manage symptoms. Though the intent is not to hasten death, this may be a foreseeable consequence
  - withdrawing or withholding life sustaining interventions (e.g. artificial ventilation or nutrition) that are keeping the patient alive but no longer wanted or indicated

Common Ethical Arguments/Opinions
- criminally prohibiting assistance in death, forces some who will eventually become too unwell to end their own lives at an earlier time and forces others to endure intolerable suffering.
- patient has the right to make autonomous choices about the time and manner of their own death
- belief that there is no ethical difference between the acts of euthanasia/assisted suicide and forgoing life-sustaining treatments
- belief that these acts benefit terminally ill patients by relieving suffering
• patient autonomy has limits
• death should be the consequence of the morally justified withdrawal of life-sustaining treatments only in cases where there is a fatal underlying condition, and it is the condition (not the withdrawal of treatment) that causes death
• an argument presented in the Carter case (see below) suggested permitting MAID will detract support for palliative care, since with proper palliative care, the number of requests for MAID would decrease. This argument was rejected in Carter v. Canada, as making people suffer to potentially improve care for others is not acceptable

Legal Aspect
• in the Carter v. Canada decision of February 2015, the criminal prohibition on assistance in suicide was ruled unconstitutional to the extent that they prohibit physician-assisted death for a competent adult person who (1) clearly consents to the termination of life and (2) has a grievous and irremediable medical condition that causes enduring suffering that is intolerable to the individual in the circumstances of his or her condition
• Bill C-14 (June 17, 2016) legalized MAID by amending the Criminal Code to create exemptions permitting medical practitioners to provide MAID, specified the eligibility criteria, safeguards, and required documentation and authorization from the Minister of Health, as well as new offences for failure to comply with the new regulations. http://www.parl.ca/DocumentViewer/en/42-1/bill/C-14/royal-assent
  • as the Bill C-14 criteria are narrower than the Carter decision, there are ongoing constitutional challenges to the MAID framework as it currently stands

Bill C-14 Criteria for MAID
• patient is eligible for publicly-funded health services in Canada
• at least 18 yr of age, and has capacity for clear and freely given consent
• grievous and irremediable medical condition: in an advanced state of irreversible decline in capability
• suffering intolerable to the patient, not relieved under conditions they consider acceptable
• natural death is reasonably foreseeable

MAID Process
1. eligibility criteria satisfied
2. patient signs and dates a written request for MAID
3. two independent witness sign the written request. Witnesses must be 18 years of age, understand the nature of MAID, and must not a) benefit (financially or otherwise) from the death, b) be an owner or operator of the healthcare facility where the patient is receiving care, c) be directly involved in the provision of health or personal care of the patient
4. HCP must inform the patient that they can withdraw their consent at any time
5. two independent assessors (MD or NP) must provide written confirmation that eligibility criteria are met
6. 10 clear days must elapse between the request and the day on which MAID is provided, unless both healthcare providers agree that a shorter period is appropriate due to the patient's imminent death or loss of capacity
7. throughout the 10 d period and immediately before providing MAID, the HCP must give the individual an opportunity to withdraw the request and ensure that the patient gives express consent to receive MAID
  • contravention of this process is an offence punishable by up to five years in prison

Acceptable Use of Palliative and End-of-Life Care
• the use of palliative sedation with opioids in end-of-life care, knowing that death may occur as an unintended consequence (principle of double effect) is distinguished from euthanasia and assisted suicide where death is the primary intent
• the appropriate withdrawal of life-support is distinguished from euthanasia and assisted suicide as it is seen as allowing the underlying disease to take its 'natural course', but this distinction may be more theoretical than real
• consent for withdrawal of life-support must be sought from the capable patient, or in case of incapable patient the SDMs, as per the Health Care Consent Act and Substitute Decisions Act, and as re-affirmed by the ruling in Cathbertson v. Rasouli in 2013, as palliative care would be instituted and consent for that would require SDM consent
• refusals of care by the patient that may lead to death as well as requests for a hastened death, ought to be carefully explored by the physician to rule out any 'reversible factors' (e.g. poor palliation, depression, poverty, ill-education, isolation) that may be hindering authentic choice
  • options and decision making at end of life: palliative care, do not resuscitate orders, refusal or withdrawal of treatment, refusal of food and drink, palliative sedation, MAID
  • decisions at end of life: informed and capacity for consent, substitute decision maker, advanced care planning (written plan, will, or medical directive) often established through a family meeting
Physician Responsibilities Regarding Death

- Physicians are required by law to complete a medical certificate of death unless the coroner needs notification; failure to report death is a criminal offence.
- **Coroner’s Act**, 1990 (specific to Ontario, similar in other provinces) requires physicians to notify a coroner or police officer if death occurs:
  - due to violence, negligence, misconduct, misadventure, or malpractice
  - during pregnancy or is attributable to pregnancy
  - suddenly and unexpectedly
  - from disease which was not treated by a legally qualified medical practitioner
  - from any cause other than disease
  - under suspicious circumstances
  - death from MAID
- Coroner investigates these deaths, as well as deaths that occur in psychiatric institutions, jails, foster homes, nursing homes, hospitals to which a person was transferred from a facility, institution or home, etc.
- In consultation with forensic pathologists and other specialists, the coroner establishes:
  - the identity of the deceased
  - where and when the death occurred
  - the medical cause of death
  - the means of death (i.e., natural, accidental, suicide, homicide, or undetermined)
- Coroners do not make decisions regarding criminality or legal responsibility
- While the Supreme Court of Canada noted that nothing in the *Carter v. Canada* decision compelled a physician to participate in MAID, the College of Physicians and Surgeons of Ontario mandatory referral policy, which has been upheld by the courts, requires physicians in Ontario to provide an effective referral if the physician conscientiously objects to MAID:
  - The impact of MAID on religious institutions’ obligation towards patients is not yet clear

### CanMEDS Competencies (Ethical/Policy Statement)

- A framework of professional competencies established by the Medical Council of Canada (MCC) as objectives for the MCC Qualifying Exam
- Further information on Medical Council of Canada objectives can be found at www.mcc.ca

### Legal Considerations

- Physicians’ conduct and competence are legally regulated to protect patients and society via mandatory membership to provincial governing bodies (e.g., the CPSO).
- Physicians are legally required to maintain a license with the appropriate authority, and are thus legally bound to outlined policies on matters of conduct within their medical practice.
- The ultimate constraint on MD behaviour with regards to unprofessionalism is conduct unbecoming a physician, such as inappropriate behaviour with colleagues, conflicts of interest, untruthfulness, unethical billing practices, and sexual impropriety with patients.

### Common Policies on Physician Conduct

- Physicians must ensure that patients have access to continuous on-call coverage and are never abandoned.
- Physicians are required to comply with the law, which include human rights laws. A failure to accommodate a disability in violation of human rights legislation, can result in the regulatory body sanctioning the physician in addition to any penalties assigned by the human rights tribunal.
- Sexual conduct with patients, even when consented to by the patient, is a serious matter that can lead to accusations of battery by the patient and provincial governing body. Important notes on this topic include:
  - Inappropriate sexual conduct includes intercourse, undue touching, references to sexual matters, sexual jokes, and physician presence when capable patients undress or dress.
  - In specified situations, physicians may have a personal relationship with a patient provided a year has passed since the last therapeutic contact.
  - Physicians are permanently prohibited from personal relationships with patients whom they saw for psychotherapy.
  - In Ontario, physicians must report any colleagues of whom they have information regarding sexual impropriety (as per CPSO Code of Ethics).
- Physicians must maintain adequate records for each patient, which include:
  - Demonstration that care has been continuous and comprehensive.
  - Minimal standards for record-keeping, including readability, diagnosis, differential diagnosis, appropriate tests and referrals, and a coherent patient record, including drugs, a cumulative patient profile, and all aspects of charting that are required for safe patient care (full standards available at www.cpso.on.ca). Another physician should be able to take over the safe care of the patient based on the record.
  - Records stored for 10 years in most jurisdictions.
• although the medical record is the property of the physician or an institution, the patient or the patient's delegate must be:
  • allowed full access to information in the medical record
  • patient or delegate must obtain access within a reasonable period of time
  • usually upon written request by the patient or patient's delegate
  • physician can charge a reasonable fee for this service
• in the hospital, physicians must ensure their own competence, respect hospital by-laws and regulations, practice only within the limits of granted privileges, cooperate with other hospital personnel, and maintain adequate hospital records

Research Ethics

• involves the systematic analysis of ethical dilemmas arising during research involving human subjects to ensure that:
  • study participants are protected
  • clinical research is conducted to serve the interests of the participants and/or society as a whole
  • major ethical dilemmas arise when a physician's obligation to the patient comes into conflict with other obligations and incentives
  • any exceptions to disclosure for therapeutic consent do not apply in an experimental situation
  • important ethical principles to consider when conducting research on human subjects are laid out in the Declaration of Helsinki, the Belmont Report, and the Tri-Council Policy Statement: Ethical Conduct on Research Involving Human Subjects

Table 5. Ethical Principles for Research Involving Human Subjects

| Patient’s participation in research should not put them at a known or probable disadvantage with respect to medical care (i.e. cannot deny participants in research ‘known effective care’, such as randomizing patients with depression to a placebo arm with no treatment) |
| Participant’s voluntary and informed choice is usually required, except in special circumstances (i.e. chart reviews without patient contact, or emergency situations for which there is no accepted or helpful standard of care and the proposed intervention is not likely to cause more harm than such patients already face) |
| Access to the treatment that is considered standard (i.e. placebo-controlled trials are generally acceptable where patients still receive the standard of care, or, if not, are informed about the placebo arm and what that entails) |
| Must employ a scientifically valid design to answer the research question (ensured via peer review, expert opinion) |
| Must demonstrate sufficient value to justify any risk posed to participants |
| Findings must be reported promptly and accurately without exaggeration, to allow practicing clinicians to draw reasonable conclusions |
| Patients must not be enticed into risky research by financial incentives and investigators must not trade the interests of patients for disproportionate recompense by a sponsor; both participants and investigators are due fair recompense for their time and efforts |
| Any significant interventional trial ought to have a data safety monitoring board that is independent of the sponsor and can ensure safety of the ongoing trial |

Physician-Industry Relations

• health care delivery in Canada involves collaboration between physicians and the pharmaceutical and health supply industries in the areas of research, education, and clinical evaluation packages (i.e. product samples)
• however, unlike physicians, pharmaceutical and health supply industries do not have a fiduciary duty to patients and are profit-driven
  • for example, the dissemination of free product samples by pharmaceutical companies is associated with increased patient preference for new drugs that are often more expensive, thus incurring a greater long-term cost for patients and the healthcare system
  • new pharmaceutical products are not always more effective than previous standard of care and may have less robust safety evidence by virtue of being new drugs
• physicians must ensure that their participation in such collaborative efforts is in keeping with their duties to their patients and society; however, physicians often struggle to properly identify situations in which a conflict of interest is present
• even seemingly innocuous gifts or other interactions (pens with pharmaceutical logo, research honoraria, meals, speaker fees, etc.) can subconsciously influence physician practices and beliefs in favour of promoted products, resulting in the prescription of medications for reasons other than their efficacy and safety profile
• gifts or free products from the pharmaceutical industry are usually inappropriate:
  • sponsorship for travel and fees for conference attendance may be accepted only where the physician is a conference presenter and not just in attendance
  • physicians receiving such sponsorship must disclose this at presentations and/or in written articles
Resource Allocation

- **Definition**: the distribution of goods and services to programs and people
- Physicians have the duty to inform patients about therapeutic options even if they are not available
- Physicians must make health care resources available to patients in a manner which is fair and equitable, without bias or discrimination
  - Need and benefit are morally relevant criteria for resource allocation
  - Gender, sexual orientation, religion, level of education, or age alone are morally irrelevant criteria. Must be weighed against need and benefit to justify equitable allocation of resources
- Ethical dilemmas that arise when deciding how best to allocate resources
  - Fair chances vs. best outcome: favouring best outcome vs. giving all patients fair access to limited resources (e.g., transplant list prioritization)
  - Priorities problem: how much priority should the sickest patients receive?
  - Aggregation problem: modest benefits to many vs. significant benefits to few
  - Democracy problem: when to rely on a fair democratic process to arrive at a decision

Guidelines for Appropriately Allocating Resources

- The physician's primary obligation is to:
  - Protect and promote the welfare and best interests of their patients
  - Choose interventions known to be beneficial on the basis of evidence of effectiveness
  - Seek the tests or treatments that will accomplish the diagnostic or therapeutic goal for the least cost
  - Advocate for one’s patients, but avoid manipulating the system to gain unfair advantage for them
  - Resolve conflicting claims for scarce resources justly, on the basis of morally relevant criteria such as need and benefit, using fair and publicly defensible procedures
  - Inform patients of the impact of cost constraints on care, but in a sensitive way
  - Seek resolution of unacceptable shortages at the level of hospital management or government

Conscientious Objection

Patients Refusing Treatment

- In accordance with the principle of autonomy, it is generally acceptable for competent patients to refuse medical interventions for themselves or others, although exceptions may occur
- The onus of justifying reasons for refusal or agreement is higher on SDMs than on capable patients
- If parents or SDMs make decisions that are clearly not in the “best interests” of an incapable child, physicians may have ethical grounds for administering treatment, depending on the acuity of the clinical situation
  - In high-acuity scenarios (e.g., refusing blood transfusion based on religious grounds for a child in hemorrhagic shock), physicians have a stronger obligation to act in the child’s best interests
  - In lower acuity scenarios (e.g., refusing childhood immunization in a developed nation) there is a stronger obligation to respect the autonomy of the decision-makers
- In 2014, a child was found not to be “a child in need of protection” when her mother refused chemotherapy and pursued traditional Indigenous healing. While this decision purported to establish a new constitutional right to Indigenous healing, the decision was amended such that “the best interests of the child are paramount.” These statements could be interpreted in contradiction with each other, so it is unclear what the current status of the law is. See Hamilton Health Sciences Centre v. DH for more information

Physicians Refusing to Provide Treatment

- Physicians may refuse to provide treatment or discontinue relationships with patients, but must ensure these patients can access services elsewhere by way of referring the patient to a willing practitioner (e.g., a pediatrician who refuses to treat an unvaccinated child should refer the family to another practice)
Indigenous Legal and Health Policy

- Indigenous peoples collectively refers to original inhabitants of Canada and their descendants: First Nations, Inuit, and Métis peoples defined in the Canadian Constitution Act, 1982
  - First Nations traditional territory encompasses all of geographic Canada and constitutes many distinct communities and languages
  - Inuit refers to original inhabitants of arctic regions including Labrador, northern Quebec, Nunavut, and Northwest Territories
  - Métis are Indigenous people of both First Nations and European heritage
  - Canada's Indian Act, 1876, defined who is considered a “status Indian” and thus eligible for programs and services by federal and provincial agencies. Non-Status First Nations, are Indigenous peoples who are not a “Registered Indian” with the federal government
  - while used by the federal government and for legal proceedings, the terms “status/non-status Indian” are paternalistic and offensive
  - the Daniels Decision, 2016, the Federal Court of Canada, deemed Métis and non-status First Nations peoples be considered “Indians” under Canadian Constitution Act but no reparations in fiduciary duty or duty to consult have been made

- Indigenous Health Policy in Canada is made up of a complicated “patchwork” of policies, legislation and agreements between federal, provincial, municipal, and Indigenous governments which is in a constant state of flux; reviewed by the National Collaborating Centre for Indigenous Health (NCCIH):
  - while some Indigenous health services are adequate, gaps and ambiguities created by complicated policy and jurisdictions have created barriers to health equity
  - for on-reserve First Nations and Inuit, the federal government finances and administers health services through the First Nations and Inuit Health Branch (FNIHB)
  - the Indian Health Policy, 1979, and Health Transfer Policy, 1989, transferred control to individual communities to negotiate with the FNIHB varying levels of health care responsibility to the community or council level
  - treaties and Self Government Agreements can define areas of jurisdiction for federal, provincial/territorial, and First Nations governments

Toronto Notes 2020
Overview of Anesthesia

anesthesia: lack of sensation/perception

Approach to Anesthesia

Pre-operative
1. pre-operative assessment
2. patient optimization

Pre-operative/Peri-operative
3. plan anesthetic
   various types of anesthesia
   pre-medication
   airway management
   monitors
   induction
   maintenance
   emergence
   tracheal extubation

Post-operative
4. post-operative care

Types of Anesthesia

• general
  • general anesthetics (GA)
  • total IV anesthesia (TIVA)

• regional
  • spinal, epidural
  • peripheral nerve block
  • IV regional

Note that different types of anesthesia can be combined (general + regional)

Pre-Operative Assessment

Purpose
• identify concerns for medical and surgical management of patient
• allow for questions to help allay any fears or concerns patient and/or family may have
• arrange further investigations, consultations and treatments for patients not yet optimized
• plan and consent for anesthetic techniques

History and Physical

History
• age, gender
• indication for surgery
• surgical/anesthetic Hx: previous anesthetics, any complications, previous intubations, post-operative N/V
• FHx: abnormal anesthetic reactions, malignant hyperthermia, pseudocholinesterase deficiency (see Uncommon Complications, A28)
• medications, allergies (see Pre-Operative Optimization: Medications, A4)
Anesthesia
Pre-Operative Assessment

PMHx
- neuro: seizures, TIA/strokes, raised ICP, spinal disease, aneurysm, conditions affecting neuromuscular junction (e.g. myasthenia gravis)
- CVS: angina/CAD, MI, CHF, HTN, valvular disease, dysrhythmias, peripheral vascular disease (PVD), conditions requiring endocarditis prophylaxis, exercise tolerance, CCS/NYHA class (see Cardiology and Cardiac Surgery, C26, C35 sidebar for New York Heart Association Classification)
- respiratory: smoking, asthma, COPD, recent upper respiratory tract infection (URTI), sleep apnea
- GI: GERD, liver disease, NPO status
- renal: acute vs. chronic renal insufficiency, dialysis, chronic kidney disease
- hematologic: anemia, coagulopathies, blood dyscrasias
- MSK: arthritides (e.g. rheumatoid arthritis, scleroderma), cervical spine pathology (e.g. cervical tumours, cervical infections/abscesses, trauma to cervical spine, previous cervical spine surgery), cervical spine instability (e.g. Trisomy 21)
- endocrine: DM, thyroid disorders, adrenal disorders
- other: morbid obesity, pregnancy, ethanol/recreational drug use

Physical Exam
- weight, height, BP, heart rate, respiratory rate, oxygen saturation
- focused physical exam of the CNS, CVS, and respiratory systems
- general assessment of nutrition, hydration, and mental status
- airway assessment is done to determine intubation difficulty (no single test is specific or sensitive) and ventilation difficulty
  - cervical spine stability and neck movement – upper cervical spine extension, lower cervical spine flexion (“sniffing the morning air” position – Figure 6, Panel C)
  - Mallampati classification
    - “3-3-2 rule”
      - 3 of patient’s own fingers can be placed between the incisors (incisor distance)
      - 3 fingers along the floor of the mandible between the mentum and hyoid bone (hyoid-mental distance)
      - 2 fingers in the superior laryngeal notch (thyroid-mouth distance)
      - thyromental distance (distance of lower mandible in midline from the mentum to the thyroid notch); <3 finger breadths (<6 cm) is associated with difficult intubation
      - mouth opening (<2 finger breadths is associated with difficult intubation)
      - anterior jaw subluxation (<1 finger breadth is associated with difficult intubation)
  - tongue size
  - dentition, dental appliances/prosthetic caps, existing chipped/loose teeth – pose aspiration risk if dislodged and must inform patients of rare possibility of damage
  - nasal passage patency (if planning nasotracheal intubation)
  - assess potential for difficult ventilation
  - examination of anatomical sites relevant to lines and blocks
    - bony landmarks and suitability of anatomy for regional anesthesia (if relevant)
    - sites for IV, CVP, and pulmonary artery (PA) catheters

Figure 1. Mallampati classification of oral opening

Figure 2. 3-3-2 Rule

Figure 3. Laryngeal views
Pre-Operative Investigations

- routine pre-operative investigations are only necessary if there are comorbidities or certain indications

Table 1. Suggested Indications for Specific Investigations in the Pre-Operative Period

American Society of Anesthesiology Classification

- common classification of physical status at the time of surgery
  - a gross predictor of overall outcome, NOT used as stratification for anesthetic risk (mortality rates)
  - ASA 1: a healthy, fit patient
  - ASA 2: a patient with mild systemic disease
    - e.g. controlled Type 2 DM, controlled essential HTN, obesity, smoker
  - ASA 3: a patient with severe systemic disease that limits activity
    - e.g. stable CAD, COPD, DM, obesity
  - ASA 4: a patient with incapacitating disease that is a constant threat to life
    - e.g. unstable CAD, renal failure, acute respiratory failure
  - ASA 5: a moribund patient not expected to survive 24 h without surgery
    - e.g. ruptured abdominal aortic aneurysm (AAA), head trauma with increased ICP
  - ASA 6: declared brain dead, a patient whose organs are being removed for donation purposes
  - for emergency declarations, add the letter E after classification (e.g. ASA 3E)

Pre-Operative Optimization

- in general, prior to elective surgery:
  - any fluid and/or electrolyte imbalance should be corrected
  - extent of existing comorbidities should be understood, and these conditions should be optimized prior to surgery
  - medications may need adjustment

Medications

- pay particular attention to cardiac and respiratory medications, opioids and drugs with many side effects and interactions
- pre-operative medications to consider
  - prophylaxis
    - risk of GE reflux: sodium citrate and/or ranitidine and/or metoclopramide 30 min-1 h prior to surgery
    - risk of infective endocarditis, GI/GU interventions: antibiotics
    - risk of adrenal suppression: steroid coverage
    - anxiety: consider benzodiazepines
    - COPD: asthma: bronchodilators
    - CAD risk factors: nitroglycerin and β-blockers
- pre-operative medications to stop
  - oral antihyperglycemics: do not take on morning of surgery
  - ACEI and angiotensin receptor blockers: do not take on the day of surgery (controversial – they increase the risk of hypotension post-induction but have not been shown to increase mortality or adverse outcomes; therefore, some people hold and some do not)
  - warfarin (consider bridging with heparin), anti-platelet agents (e.g. clopidogrel), Xa inhibitor, direct thrombin inhibitors

Continuation versus Discontinuation of Antiplatelet Therapy for Bleeding and Ischaemic Events in Adults Undergoing Non-Cardiac Surgery

Objective: To compare continuation vs. discontinuation of antiplatelet therapy on the occurrence of bleeding and ischaemic events in adults undergoing non-cardiac surgery.

Methods: RCTs in Cochrane Central Register of Controlled Trials, MEDLINE, and Embase that compared adults taking single or dual antiplatelet therapy for at least two weeks, including patients compared adults taking single or dual antiplatelet therapy for at least two weeks. Included: general, spinal, and regional anesthesia and excluded minor procedures involving only local anesthesia/sedation.

Results: 5 trials, 866 adult patients. Continuation or discontinuation had no difference on mortality at 30 d post-op (RR 1.21, 95% CI 0.34-4.27), blood loss (RR 1.37, 95% CI 0.83-2.26), or ischaemic events within 30 d of surgery (RR 0.97, 95% CI 0.55-1.71).

Conclusions: Moderate evidence supporting continuation or discontinuation of antiplatelet therapy makes no difference on bleeding requiring transfusion. Low evidence supporting no difference in mortality or ischaemic events.
• discuss perioperative use of ASA, NSAIDs with surgeon (+ patient's cardiologist/internist)
• in patients undergoing non-cardiac surgery, starting or continuing low-dose ASA in the perioperative period does not appear to protect against post-operative MI or death, but increases the risk of major bleeding
  – note: this does not apply to patients with bare metal stents or drug-eluting coronary stents
• herbal supplements: stop one week prior to elective surgery (ephedra, garlic, ginko, ginseng, kava, St. John's Wort, Valerian, Echinacea)
• pre-operative medications to adjust
  • insulin (consider insulin/dextrose infusion or holding dose), prednisone, bronchodilators

**Hypertension**

• BP <180/110 is not an independent risk factor for perioperative cardiovascular complications
• target sBP <180 mmHg, dBP <110 mmHg
• BP <180/110 is not an independent risk factor for perioperative cardiovascular complications
• assess for end-organ damage and treat accordingly

**Coronary Artery Disease**

• ACC/AHA Guidelines (2014) recommend that at least 60 d should elapse after a MI before a non-cardiac surgery in the absence of a coronary intervention
  • this period carries an increased risk of re-infarction/death
  • if operative procedure is essential and cannot be delayed then invasive intra- and post-operative ICU monitoring is required to reduce the above risk
• mortality with perioperative MI is 20-50%
• perioperative β-blockers
  • may decrease cardiac events and mortality (but increases risk of perioperative strokes)
  • continue β-blocker if patient is routinely taking it prior to surgery
  • consider initiation of β-blocker in:
    • patients with CAD or indication for β-blocker
    • intermediate or high risk surgery, especially vascular surgery

**Respiratory Diseases**

• smoking
  • adverse effects: altered mucus secretion and clearance, decreased small airway calibre, altered oxygen carrying capacity, increased airway reactivity, and altered immune response
  • abstain at least 8 wk pre-operatively if possible
  • if unable, abstaining even 24 h pre-operatively has been shown to increase oxygen availability to tissues
• asthma
  • pre-operative management depends on degree of baseline asthma control
  • increased risk of bronchospasm from intubation
  • administration of short course (up to 1 wk) pre-operative corticosteroids and inhaled β2-agonists decreases the risk of bronchospasm and does not increase the risk of infection or delay wound healing
  • avoid non-selective β-blockers due to risk of bronchospasm (cardioselective β-blockers (metoprolol, atenolol) do not increase risk in the short-term)
  • delay elective surgery for poorly controlled asthma (increased cough or sputum production, active wheezing)
  • ideally, delay elective surgery by a minimum of 6 wk if patient develops URTI
• COPD
  • anesthesia, surgery (especially abdominal surgery, in particular upper abdominal surgery) and pain predispose the patient to atelectasis, bronchospasm, pneumonia, prolonged need for mechanical ventilation, and respiratory failure
  • pre-operative ABG is needed for all COPD stage II and III patients to assess baseline respiratory acidosis and plan post-operative management of hypercapnea
  • cancel/delay elective surgery for acute exacerbation

**Aspiration**

• increased risk of aspiration with:
  • decreased LOC (drugs/alcohol, head injury, CNS pathology, trauma/shock)
  • delayed gastric emptying (non-fasted within 8 h, diabetes, narcotics)
  • decreased sphincter competence (GERD, hiatus hernia, nasogastric tube, pregnancy, obesity)
  • increased abdominal pressure (pregnancy, obesity, bowel obstruction, acute abdomen)
  • unprotected airway (laryngeal mask vs. ETT)
• management
  • manage risk factors if possible
  • utilize protected airway (i.e. endotracheal tube)
  • reduce gastric volume and acidity
  • delay inhibiting airway reflexes with muscular relaxants
  • employ rapid sequence induction (see Rapid Sequence Induction, A15)

**β-blockers**

• β1-receptors are located primarily in the heart and kidneys
• β2-receptors are located in the smooth muscle (i.e. bronchi, uterus)
• Non-selective β-blockers block β1 and β2-receptors (labetalol*, carvedilol**, nadolol). Caution is required with non-selective β-blockers, particularly in patients with respiratory conditions where β2 blockade can result in airway reactivity
  *labetalol is both an α- and β-blocker
  **carvedilol is also both an alpha and beta blocker

Perioperative β-blockers for Preventing Surgery-related Mortality and Morbidity

Cochrane DB Syst Rev 2018; CD004476

Objectives: Effects of perioperative β-blockers for prevention of surgery-related mortality and morbidity in patients undergoing any type of surgery while under general anesthesia.

Outcomes:
Cardiac surgery: Perioperative β-blockers associated with reduced supraventricular (RR 0.44, 95% CI 0.36-0.53) and ventricular (RR 0.37, 95% CI 0.24-0.56) arrhythmias in the aftermath of surgery. Effect on mortality, AMI, stroke, CHF, hypotension, and bradycardia unclear.

Non-cardiac surgery: Perioperative β-blockers associated with decreased incidence of supraventricular arrhythmias (RR 0.73, 95% CI 0.57-0.94) and AMI (RR 0.73, 95% CI 0.61-0.87). However, this is potentially offset by increased all-cause mortality (RR 1.23, CI 0.95-1.58) with potential increase in stroke rate (RR 1.59, 95% CI 0.92-2.71).
Fasting Guidelines

Fasting Guidelines Prior to Surgery (Canadian Anesthesiologists’ Society)
- before elective procedures, the minimum duration of fasting should be:
  - 8 h after a meal that includes meat, fried or fatty foods
  - 6 h after a light meal (such as toast or crackers) or after ingestion of infant formula or non-human milk
  - 4 h after ingestion of breast milk
  - 2 h after clear fluids (water, black coffee, tea, carbonated beverages, juice without pulp)

Hematological Disorders

- history of congenital or acquired conditions (sickle cell anemia, factor VIII deficiency, ITP, liver disease)
- evaluate hemoglobin, hematocrit and coagulation profiles when indicated (see Table 1)
- anemia
  - pre-operative treatments to increase hemoglobin (PO or IV iron supplementation, erythropoietin or pre-admission blood collection in certain populations)
- coagulopathies
  - discontinue or modify anticoagulation therapies (warfarin, clopidogrel, ASA, apixaban, dabigatran) in advance of elective surgeries
  - administration of reversal agents if necessary: vitamin K, FFP, prothrombin complex concentrate, recombinant activated factor VII

Endocrine Disorders

- Diabetes Mellitus (DM)
  - clarify type 1 vs. type 2
  - clarify treatment – oral anti-hyperglycemics and/or insulin
  - assess glucose control with history and HbA1c; well controlled diabetics have more stable glucose levels intraoperatively
  - end organ damage: be aware of damage to cardiovascular, renal, and central, peripheral and autonomic nervous systems
- preoperative guidelines for DM:
  - 1. verify target blood glucose concentration with frequent glucose monitoring: <10 mmol/L in critical patients, <7.8 mmol/L in stable patients)
  - 2. use insulin therapy to maintain glycemic goals
  - 3. hold biguanides, α-glucosidase inhibitors, thiazolidinediones, sulfonylureas and GLP-1 agonists on the morning of surgery
  - 4. consider cancelling nonemergency procedures if patient presents with metabolic abnormalities (DKA, HHS, etc.) or glucose reading above 22.2-27.7 mmol/L
  - formulate intraoperative glucose management plan based on type (1 vs. 2), glucose control, and extent of end organ damage
- hyperthyroidism and hypothyroidism
  - hyperthyroidism: can experience sudden release of thyroid hormone (thyroid storm) if not treated or well-controlled pre-operatively; treatment: β-blockers and pre-operative prophylaxis
  - adrenocortical insufficiency (Addison’s, exogenous steroid use)
  - consider intraoperative steroid supplementation

Obesity and Obstructive Sleep Apnea

- assess for co-morbid conditions in obese patient (independent risk factor for CVD, DM, OSA, cholelithiasis, HTN)
- previously undiagnosed conditions may require additional testing to characterize severity
- severity of OSA may be determined from sleep studies and level of pressure prescribed for home CPAP device
- both obesity and OSA independently increase risk of difficult ventilation, intubation and post-operative respiratory complications

Monitoring

Canadian Guidelines to the Practice of Anesthesia and Patient Monitoring
- an anesthetist present: “the only indispensable monitor”
- a completed pre-anesthetic checklist: including ASA class, NPO policy, Hx and investigations
- a perioperative anesthetic record: HR and BP every 5 min, O2 saturation, End Tidal CO2, dose and route of drugs and fluids
- continuous monitoring: see Routine Monitors for All Cases, A7

Preoperative Anemia and Postoperative Outcomes in Non-Cardiac Surgery: a Retrospective Cohort Study
Lancet 2011; 378: 1396-1407
Objectives: Assess effect of preoperative anemia on 30 d postoperative morbidity and mortality in patients undergoing major non-cardiac surgery.
Methods: Patients undergoing major non-cardiac surgery in 2008 from the American College of Surgeons’ National Surgical Quality Improvement Program database.
Results: 227 425 adult patients. Postoperative mortality at 30 d was higher in patients with anemia than those without (OR 1.42, 95% CI 1.30-1.54).
Outcomes: Preoperative anemia, even to a mild degree, is independently associated with an increased risk of 30 d morbidity and mortality.
Routine Monitors for All Cases
- pulse oximeter, BP monitor, electrocardiography, capnography (required for general anesthesia and deep procedural sedation, Ramsey Sedation Scale 4-6), and an agent-specific anesthetic gas monitor when inhalational anesthetic agents are used
- the following must also be available: temperature probe, peripheral nerve stimulator, stethoscope, appropriate lighting, spirometry, manometer to measure endotracheal tube cuff pressure

Elements to Monitor
- anesthetic depth
  - end-tidal inhaled anesthetic monitoring and EEG monitoring, such as a Bispectral Index monitor, can be used as assessments of anesthetic depth
  - inadequate: blink reflex present when eyelashes lightly touched, HTN, tachycardia, tearing or sweating. However, these findings are non-specific
  - excessive: hypotension, bradycardia
- oxygenation: pulse oximetry, FiO₂
- ventilation: verify correct position of ETT, chest excursions, breath sounds, ETCO₂ analysis, end tidal inhaled anesthesia analysis
- circulation: heart rate, rhythm, BP, telemetry, oximetry, pulmonary capillary wedge pressure
- temperature
- hourly urine output

Airway Management

Airway Anatomy
- resistance to airflow through nasal passages accounts for approximately 2/3 of total airway resistance
- pharyngeal airway extends from posterior aspect of the nose to cricoid cartilage
- glottic opening (triangular space formed between the true vocal cords) is the narrowest segment of the laryngeal opening in adults
- the glottic opening is the space through which one visualizes proper placement of the ETT
- the trachea begins at the level of the thyroid cartilage, C6, and bifurcates into the right and left main bronchi at T4-T5 (approximately the sternal angle)

Methods of Supporting Airways
1. non-definitive airway (patent airway)
   - jaw thrust/chin lift
   - oropharyngeal and nasopharyngeal airway
   - bag mask ventilation
   - LMA
2. definitive airway (patent and protected airway)
   - ETT
   - surgical airway (cricothyotomy or tracheostomy)
Table 2. Methods of Supporting the Airway

Preparation for Intubation
- Failed attempts at intubation can make further attempts more difficult due to tissue trauma
- Plan, prepare, and assess for potential difficulties (see Pre-Operative Assessment, A2)
- Ensure equipment is available and working (test ETT cuff, check laryngoscope light and suction, machine check)
- Pre-oxygenate/denitrogenate: patient breathes 100% O₂ for 3-5 min or for 4-8 vital capacity breaths
- May need to suction mouth and pharynx first

Proper Positioning for Intubation
- Align the three axes (mouth, pharynx, and larynx) to allow visualization from oral cavity to glottis
  - Sniffing position: flexion of lower C-spine (C5-C6), bow head forward, and extension of upper C-spine at atlanto-occipital joint (C1), nose in the air
  - Contraindicated in known/suspected C-spine fracture/instability
  - Poor/no view of glottic opening can be remediated by anterior laryngeal pressure
  - Laryngoscope tip placed in the epiglottic vallecula in order to visualize cord
Tube Insertion
- laryngoscopy and ETT insertion can incite a significant sympathetic response via stimulation of cranial nerves 9 and 10 due to a "foreign body reflex" in the trachea, including tachycardia, dysrhythmias, myocardial ischemia, increased BP, and coughing
- a malpositioned ETT is a potential hazard for the intubated patient
  - if too deep, may result in right endobronchial intubation, which is associated with left-sided atelectasis and right-sided tension pneumothorax
  - if too shallow, may lead to accidental extubation, vocal cord trauma, or laryngeal paralysis as a result of pressure injury by the ETT cuff
- the tip of ETT should be located at the midpoint of the trachea at least 2 cm above the carina and the proximal end of the cuff should be placed at least 2 cm below the vocal cords
- approximately 20-23 cm mark at the right corner of the mouth for men and 19-21 cm for women

Confirmation of Tracheal Placement of Endotracheal Tube
- direct
  - visualization of ETT passing through cords
  - bronchoscopic visualization of ETT in trachea
- indirect
  - ETCO₂ in exhaled gas measured by capnography – a mandatory method for confirming the ETT is in the airway
  - auscultate for equal breath sounds bilaterally and absent breath sounds over epigastrium
  - bilateral chest movement, condensation of water vapour in ETT visible during exhalation and no abdominal distention
  - refilling of reservoir bag during exhalation
  - CXR (rarely done): only confirms position of the tip of ETT and not whether the ETT is in the trachea
- esophageal intubation suspected when:
  - ETCO₂ zero or near zero on capnograph
  - abnormal sounds during assisted ventilation
  - impairment of chest excursion
  - hypoxia/cyanosis
  - presence of gastric contents in ETT
  - breath sounds heard when auscultating over epigastrium/LUQ
  - distention of stomach/epigastrium with ventilation

Complications During Laryngoscopy and Intubation
- dental damage
- laceration (lips, gums, tongue, pharynx, vallecula, esophagus)
- laryngeal trauma
- esophageal or endobronchial intubation
- accidental extubation
- insufficient cuff inflation or cuff laceration: results in leaking and aspiration
- laryngospasm (see Extubation, A20, for definition)
- bronchospasm

Difficult Airway
- difficulties with bag-mask ventilation, supraglottic airway, laryngoscopy, passage of ETT through the cords, infraglottic airway or surgical airway
- algorithms exist for difficult airways (Can J Anesth 2013;60:1119-1138), see Appendices, A30
- pre-operative assessment (history of previous difficult airway, airway examination) and pre-oxygenation are important preventative measures
- if difficult airway expected, consider:
  - awake intubation
  - intubating with bronroscope, trachlight (lighted stylet), fibre optic laryngoscope, glidescope, etc.
- if intubation unsuccessful after induction:
  1. CALL FOR HELP
  2. ventilate with 100% O₂ via bag and mask
  3. consider returning to spontaneous ventilation and/or waking patient
- if bag and mask ventilation inadequate:
  1. CALL FOR HELP
  2. attempt ventilation with oral airway
  3. consider/attempt LMA
  4. emergency invasive airway access (e.g. rigid bronchoscope, cricothyotomy, or tracheostomy)

Differential Diagnosis of Poor Bilateral Breath Sounds after Intubation
- DOPE
  - Displaced ETT
  - Obstruction
  - Pneumothorax
  - Esophageal intubation

Cormack-Lehane Classification of Laryngeal View (Figure 3)
- Grade 1: all laryngeal structures revealed
- Grade 2: posterior laryngeal 2A (posterior vocal folds) 2B (arytenoids)
- Grade 3: Larynx concealed, only epiglottis
- Grade 4: Neither glottis nor epiglottis

If you encounter difficulty with tracheal intubation, oxygenation is more important than intubation
Oxygen Therapy

- in general, the goal of oxygen therapy is to maintain arterial oxygen saturation (SaO₂) at a minimum, >90%
- small decrease in saturation below SaO₂ of 90% corresponds to a large drop in PaO₂
- in intubated patients, oxygen is delivered via the ETT
- in patients not intubated, there are many oxygen delivery systems available; the choice depends on oxygen requirements (FiO₂) and the degree to which precise control of delivery is needed
- cyanosis can be detected at SaO₂ <85%, frank cyanosis at SaO₂ = 67%

Low Flow Systems
- provide O₂ at flows between 0-10 L/min
- acceptable if tidal volume 300-700 mL, respiratory rate (RR) <25, consistent ventilation pattern
- dilution of oxygen with room air results in a decrease in FiO₂
- an increase in minute ventilation (tidal volume x RR) results in a decrease in FiO₂
- e.g. nasal cannula (prongs)
  - well tolerated if flow rates <5-6 L/min; drying of nasal mucosa at higher flows
  - nasopharynx acts as an anatomic reservoir that collects O₂
  - delivered oxygen concentration (FiO₂) can be estimated by adding 4% for every additional litre of O₂ delivered
  - provides FiO₂ of 24-44% at O₂ flow rates of 1-6 L/min

Reservoir Systems
- use a volume reservoir to accumulate oxygen during exhalation thus increasing the amount of oxygen available for the next breath
- simple face mask
  - covers patient's nose and mouth and provides an additional reservoir beyond nasopharynx
  - fed by small bore O₂ tubing at a rate of at least 6 L/min to ensure that exhaled CO₂ is flushed through the exhalation ports and not rebreathed
  - provides FiO₂ of 55% at O₂ flow rates of 10 L/min
- non-rebreather mask
  - a reservoir bag and a series of one-way valves prevent expired gases from re-entering the bag during the exhalation phase, the bag accumulates with oxygen
  - provides FiO₂ of 80% at O₂ flow rates of 10-15 L/min

High Flow Systems
- generate flows of up to 50-60 L/min
- meet/exceed patient's inspiratory flow requirement
- deliver consistent and predictable concentration of O₂
- Venturi mask
  - delivers specific FiO₂ by varying the size of air entrainment
  - oxygen concentration determined by mask's port and NOT the wall flow rate
  - enables control of gas humidity
  - FiO₂ ranges from 24-50%

Ventilation
- ventilation is maintained with PPV in patients given muscle relaxants
- assisted or controlled ventilation can also be used to assist spontaneous respirations in patients not given muscle relaxants as an artificial means of supporting ventilation and oxygenation

Mechanical Ventilation
- indications for mechanical ventilation
  - apnea
  - hypoventilation/acute respiratory acidosis
  - intraoperative positioning limiting respiratory excursion (e.g. prone, Trendelenburg)
  - required hyperventilation (to lower ICP)
  - deliver positive end expiratory pressure (PEEP)
  - increased intrathoracic pressure (e.g. laparoscopic procedure)
- complications of mechanical ventilation
  - airway complications
    - tracheal stenosis, laryngeal edema
    - alveolar complications
    - ventilator-induced lung injury (barotrauma, volutrauma, atelectrauma), ventilator-associated pneumonia (nosocomial pneumonia), inflammation, auto-PEEP, patient-ventilator asynchrony
    - cardiovascular complications
    - reduced venous return (secondary to increased intrathoracic pressure), reduced cardiac output, hypotension
  - changes in peak pressures in ACV and tidal volumes in PCV may reflect changes in lung compliance and/or airway resistance – patient may be getting better or worse
  - Positive End Expiratory Pressure (PEEP)
    - Positive pressure applied at the end of ventilation that helps to keep alveoli open, decreasing V/Q mismatch
    - Used with all invasive modes of ventilation
  - Tracheostomy
    - Tracheostomy should be considered in patients who require ventilator support for extended periods of time
    - Shown to improve patient comfort and give patients better ability to participate in rehabilitation activities
Airway Management

- neuromuscular complications
  - muscle atrophy
  - increased intracranial pressure
- metabolic
  - decreased CO2 due to hyperventilation
  - alkalemia with over correction of chronic hypercarbia

**Ventilator Strategies**
- mode and settings are determined based on patient factors (e.g. ideal body weight, compliance, resistance) and underlying reason for mechanical ventilation
- hypoxic respiratory failure: ventilator provides supplemental oxygen, recruits atelectatic lung segments, helps improve V/Q mismatch, and decreases intrapulmonary shunt
- hypercapnic respiratory failure: ventilator augments alveolar ventilation; may decrease the work of breathing, allowing respiratory muscles to rest

**Modes of Ventilation**
- assist-control ventilation (ACV) or volume control (VC)
  - every breath is delivered with a pre-set tidal volume and rate or minute ventilation
  - extra controlled breaths may be triggered by patient effort; if no effort is detected within a specified amount of time the ventilator will initiate the breath
- pressure control ventilation (PCV)
  - a minimum frequency is set and patient may trigger additional breaths above the ventilator
  - all breaths delivered at a preset constant inspiratory pressure
  - in traditional PCV, tidal volume is not guaranteed thus changes in compliance and resistance affect tidal volume
- synchronous intermittent mandatory ventilation (SIMV)
  - ventilator provides controlled breaths (either at a set volume or pressure depending on whether in VC or PCV, respectively)
  - patient can breathe spontaneously (these breaths may be pressure supported) between controlled breaths
- pressure support ventilation (PSV)
  - patient initiates all breaths and the ventilator supports each breath with a pre-set inspiratory pressure
  - useful for weaning off ventilator
- high-frequency oscillatory ventilation (HFOV)
  - high breathing rate (up to 900 breaths/min in an adult), very low tidal volumes
  - used commonly in neonatal and pediatric respiratory failure
  - occasionally used in adults when conventional mechanical ventilation is failing
- non-invasive positive pressure ventilation (NPPV)
  - achieved without intubation by using a nasal or face mask
  - BiPAP: increased pressure (like PSV) on inspiration and lower constant pressure on expiration (i.e. PEEP)
  - CPAP: delivers constant pressure on both inspiration and expiration

**Monitoring Ventilatory Therapy**
- Pulse oximetry, end-tidal CO2 concentration
- Regular arterial blood gases
- Assess tolerance regularly

**Causes of Intraoperative Hypoxemia**
- Inadequate Oxygen Supply
  - e.g. breathing system disconnection, obstructed or malpositioned ETT, leaks in the anesthetic machine, loss of oxygen supply
- Hypoventilation
- Ventilation-Perfusion Inequalities
  - e.g. atelectasis, pneumonia, pulmonary edema, pneumothorax
- Reduction in Oxygen Carrying Capacity
  - e.g. anemia, carbon monoxide poisoning, methemoglobinemia, hemoglobinopathy
- Leftward Shift of the Hemoglobin-Oxygen Saturation Curve
  - e.g. hypothermia, decreased 2,3-BPG, alkalosis, hypocarbia, carbon monoxide poisoning

**Right-to-Left Cardiac Shunt**

**Figure 9. The anesthesia circuit**
Intraoperative Management

Temperature

Causes of Hypothermia (<36.0°C)
- intraoperative temperature losses are common (e.g. 90% of intraoperative heat loss is transcutaneous), due to:
  - OR environment (cold room, IV fluids, instruments)
  - open wound
  - prevent with forced air warming blanket and warmed IV fluids

Causes of Hyperthermia (>37.5-38.3°C)
- drugs (e.g. atropine)
- blood transfusion reaction
- infection/sepsis
- medical disorder (e.g. thyrotoxicosis)
- malignant hyperthermia (see Uncommon Complications, A28)
- over-zealous warming efforts

Heart Rate

Cardiac Arrest
- pulseless arrest occurs due to 4 cardiac rhythms divided into shockable and non-shockable rhythms
  - shockable: ventricular fibrillation (VF) and ventricular tachycardia (VT)
  - non-shockable: asystole and pulseless electrical activity (PEA)
- for VF/VT, key to survival is good early CPR and defibrillation
- for asystole/PEA, key to survival is good early CPR and exclusion of all reversible causes
- reversible causes of PEA arrest (5 Hs and 5 Ts)
  - 5 Hs: hypothermia, hypovolemia, hypoxia, hydrogen ions (acidosis), hypothyroidism/acidemia
  - 5 Ts: tamponade (cardiac), thrombosis (pulmonary), thrombosis (coronary), tension pneumothorax, toxins (overdose/poisoning)
- when a patient sustains a cardiac arrest during anesthesia, it is important to remember that there are other causes on top the Hs and Ts to consider (i.e. local anesthetic systemic toxicity (LAST), excessive anesthetic dosing and others)
- for management of cardiac arrest, see Appendices, A32

Intraoperative Tachycardia
- tachycardia = HR >150 bpm; divided into narrow complex supraventricular tachycardias (SVT) or wide complex tachycardias
- SVT: sinus tachycardia, atrial fibrillation/flutter, accessory pathway mediated tachycardia, paroxysmal atrial tachycardia
- wide complex tachycardia: VT, SVT with aberrant conduction
- causes of sinus tachycardia
  - shock/hypovolemia/blood loss
  - anxiety/pain/light anesthesia
  - full bladder
  - anemia
  - febrile illness/sepsis
  - drugs (e.g. atropine, cocaine, dopamine, epinephrine, ephedrine, isoflurane, isoproterenol, pancuronium) and withdrawal
  - Addisonian crisis, hypoglycemia, transfusion reaction, malignant hyperthermia
- for management of tachycardia, see Appendices, A33

Intraoperative Bradycardia
- bradycardia = HR <50 bpm; most concerning are 2nd degree (Mobitz type II) and 3rd degree heart block, which can both degenerate into asystole
- causes of sinus bradycardia
  - increased parasympathetic tone vs. decreased sympathetic tone
  - must rule out hypoxemia
  - arrhythmias (see Cardiology and Cardiac Surgery, C16)
  - baroreceptor reflex due to increased ICP or increased BP
  - vagal reflex (oculocardiac reflex, carotid sinus reflex, airway manipulation)
  - drugs (e.g. suprachoroidal hemorrhage, opioids, edrophonium, neostigmine, halothane, digoxin, β-blockers)
  - high spinal/epidural anesthesia
- for management of bradycardia, see Appendices, A33
Blood Pressure

Causes of Intraoperative Hypotension/Shock
- shock: condition characterized by inability of cardiovascular system to maintain adequate end-organ perfusion and delivery of oxygen to tissues
  a) hypovolemic/hemorrhagic shock
    - most common form of shock, due to decrease in intravascular volume
  b) obstructive shock
    - obstruction of blood into or out of the heart
    - increased JVP, distended neck veins, increased systemic vascular resistance, insufficient cardiac output (CO)
      - e.g. tension pneumothorax, cardiac tamponade, pulmonary embolism (and other emboli – i.e. fat, air)
  c) cardiogenic shock
    - increased JVP, distended neck veins, increased systemic vascular resistance, decreased CO
      - e.g. myocardial dysfunction, dysrhythmias, ischemia/infarct, cardiomyopathy, acute valvular dysfunction
  d) septic shock
    - see Infectious Diseases, ID19
  e) spinal/neurogenic shock
    - decreased sympathetic tone
    - hypotension without tachycardia or peripheral vasoconstriction (warm skin)
  f) anaphylactic shock
    - see Emergency Medicine, ER3
  g) drugs
    - vasodilators, high spinal anesthetic interfering with sympathetic outflow
  h) other
    - transfusion reaction, Addisonian crisis, thyrotoxicosis, hypothyroid, aortocaval syndrome
    - see Hematology and Endocrinology

Causes of Intraoperative Hypertension
- inadequate anesthesia causing pain and anxiety
- pre-existing HTN, coarctation, or preeclampsia
- hypoxemia/hypercarbia
- hypervolemia
- increased intracranial pressure
- full bladder
- drugs (e.g. ephedrine, epinephrine, cocaine, phenylephrine, ketamine) and withdrawal
- allergic/anaphylactic reaction
- hypermetabolic states: malignant hyperthermia, neuroleptic malignant syndrome, serotonin syndrome, thyroid storm, pheochromocytoma (see Endocrinology, E37)

Fluid Balance and Resuscitation
- total requirement = maintenance + deficit + ongoing loss
- in surgical settings, this formula must take into account multiple factors including pre-operative fasting/ decreased fluid intake, increased losses during or before surgery, fluids given with blood products and medications
- increasingly, Enhanced Recovery After Surgery protocols recommend consumption of clear fluids up to two hours prior to surgery
- both inadequate fluid resuscitation AND excessive fluid administration increases morbidity post-operatively

What is the Maintenance?
- average healthy adult requires approximately 2500 mL water/d
  - 200 mL/d GI losses
  - 800 mL/d insensible losses (respiration, perspiration)
  - 1500 mL/d urine (beware of renal failure)
- replacement of ‘third space’ losses is not warranted
- maintenance should not exceed 3ml/kg/hr
- increased requirements with fever, sweating, GI losses (vomiting, diarrhea, NG suction), renal insufficiency, hyperventilation, and polyuric renal disease
- decreased requirements with anuria/oliguria, SIADH, highly humidified atmospheres, and CHF
- maintenance electrolytes
  - Na+: 3 mEq/kg/d
  - K+: 1 mEq/kg/d
- 50 kg patient maintenance requirements
  - fluid = 40 + 20 + 30 = 90 mL/h = 2160 mL/d = 2.16 L/d
  - Na+ = 150 mEq/d (therefore 150 mEq / 2.16 L/d = 69 mEq/L)
  - K+ = 50 mEq/d (therefore 50 mEq / 2.16 L/d = 23 mEq/L)
- above patient’s requirements roughly met with 2/3 D5W, 1/3 NS
- 2/3 + 1/3 at 100 mL/h with 20 mEq KCl per litre
- 4-2-1 rule: 4 mL/h first 10 kg, 2 mL/h next 10 kg, 1 mL/h for every kg after to calculate maintenance fluid requirement
- may also add 40 kg to weight for adults to calculate maintenance fluid requirement in mL/h
What is the Deficit?
- Patients should be adequately hydrated prior to anesthesia
- Total body water (TBW) = 60% or 50% of total body weight for an adult male or female, respectively (e.g., for a 70 kg adult male TBW = 70 x 0.6 = 42 L)
- Total Na⁺ content determines ECF volume; [Na⁺] determines ICF volume
- Hypovolemia due to volume contraction
  - Extra-renal Na⁺ loss
    - GI: vomiting, NG suction, drainage, fistulae, diarrhea
    - Skin/resp: insensible losses (fever), sweating, burns
    - Vascular: hemorrhage
    - Renal Na⁺ and H₂O loss
    - Diuretics
    - Osmotic diuresis
    - Hypoaldosteronism
    - Salt-wasting nephropathies
    - Renal H₂O loss
    - Diabetes insipidus (central or nephrogenic)
    - Hypovolemia with normal or expanded ECF volume
    - Decreased CO
    - Redistribution
      - Hypoalbuminemia: cirrhosis, nephrotic syndrome
      - Capillary leakage: acute pancreatitis, rhabdomyolysis, ischemic bowel, sepsis, anaphylaxis
- Replace water and electrolytes as determined by patient's needs
- With chronic hyponatremia, correction must be done gradually over >48 h to avoid central pontine myelinolysis

What are the Ongoing Losses?
- Traditionally thought that fluid loss during surgery resulted from blood loss, losses from Foley catheter, NG, surgical drains, and third spacing (sequestration of fluid into other body compartments such as GI, lung, evaporation)
- Fluid therapy accounting for these losses often resulted in excess crystalloid administration
- Goal-directed fluid regimens associated with lower rate of post-op complications compared to pre-determined calculations

**IV Fluids**
- Replacement fluids include crystalloid and colloid solutions
- IV fluids improve perfusion but NOT O₂ carrying capacity of blood

**Initial Distribution of IV Fluids**
- H₂O follows ions/molecules to their respective compartments

**Crystalloid Infusion**
- Salt-containing solutions that distribute only within ECF
- Consensus guidelines recommend use of balanced crystalloid (i.e., Ringer's lactate) over normal saline for routine replacement and resuscitation
- Maintain euvolemia in patient with blood loss: 3 mL crystalloid infusion per 1 mL of blood loss for volume replacement (i.e., 3:1 replacement)
- If large volumes are to be given, use balanced fluids such as Ringer's lactate or Plasmalyte®, as too much normal saline (NS) may lead to hyperchloremic metabolic acidosis

**Colloid Infusion**
- Includes protein colloids (albumin and gelatin solutions) and non-protein colloids (dextran and starches e.g., hydroxyethyl starch [HES])
- Distributes within intravascular volume
- 1:1 ratio (infusion:blood loss) only in terms of replacing intravascular volume
- The use of HES solutions is controversial because of recent RCTs and meta-analyses highlighting their renal (especially in septic patients) and coagulopathic side effects, as well as a lack of specific indications for their use
  - Colloids are being used based on mechanistic and experimental evidence but there is a paucity of definitive studies investigating their safety and efficacy; routine use of colloids should be avoided

**Colloids vs. Crystalloids for Fluid Resuscitation in Critically Ill People**
Cochrane DB Syst Rev 2018:CD000567
Objectives: To assess effect of colloids vs. crystalloids in critically ill patients on mortality, need for transfusions or renal replacement therapy, and adverse events.
Methods: Systematic review of RCTs and quasi-RCTs involving trauma, burns, or medical conditions (i.e. sepsis). Searched CENTRAL, MEDLINE, and Embase.
Outcomes: 69 studies, 30,030 participants. Starches, dextrans, albumin or FFP (moderate-certainty evidence), or gelatins (low-certainty evidence) vs. crystalloids has no difference on mortality. Starches slightly increase the need for blood transfusion (moderate-certainty evidence), and albumin or FFP may make little or no difference to the need for renal replacement therapy (low-certainty evidence). Evidence for blood transfusions for dextrans, and albumin or FFP, is uncertain.
### Induction

#### Routine Induction vs. Rapid Sequence Induction

- Routine induction is the standard in general anesthesia, however a RSI is indicated in patients at risk of regurgitation/aspiration (see Aspiration, A5).
- RSI uses pre-determined doses of induction drugs given in rapid succession to minimize the time patient is at risk for aspiration (e.g. from the time they are unconscious without an ETT until the time when the ETT is in and the cuff inflated).

### Blood Products

- see Hematology, H52

### Calculating Acceptable Blood Losses (ABL)

- Blood volume
  - term infant 80 mL/kg
  - adult male 70 mL/kg
  - adult female 60 mL/kg
- Calculate estimated blood volume (EBV) (e.g. in a 70 kg male, approx. 70 mL/kg)
  \[ \text{EBV} = 70 \times 70 = 4900 \text{ mL} \]
- Decide on a transfusion trigger, i.e. the Hb level at which you would begin transfusion, (e.g. 70 g/L for a person with Hb(i) = 150 g/L)
  \[ \text{Hb(i)} = 70 \times \frac{150}{21} = 2613 \text{ mL} \]
- Therefore in order to keep the Hb level above 70 g/L, RBCs would have to be given after approximately 2.6 L of blood has been lost

### Rocuronium versus Succinylcholine for Rapid Sequence Induction Intubation

**Objective:** Whether rocuronium creates intubating conditions comparable to those of succinylcholine during RSI intubations.

**Methods:** Systematic review of RCTs or CCTs with a dose of at least 0.6 mg/kg for rocuronium and 1 mg/kg for succinylcholine.

**Results:** 50 trials, 4151 participants.

**Succinylcholine** was superior to rocuronium for achieving excellent intubating conditions (RR 0.97, 95% CI 0.95-0.99) and clinically acceptable achieving excellent intubating conditions (RR 0.86, 95% CI 0.81-0.92) and clinically acceptable intubating conditions comparable to those of succinylcholine.

**Conclusion:** Succinylcholine created superior intubating conditions to rocuronium in achieving excellent intubation conditions (RR 0.97, 95% CI 0.95-0.99).
**Induction Agents**

- induction in general anesthesia may be achieved with intravenous agents, volatile inhalation agents, or both

**Intravenous Agents**
- IV induction agents are non-opioid drugs used to provide hypnosis, amnesia and blunt reflexes
- these are initially used to draw the patient into the maintenance phase of general anesthesia rapidly, smoothly and with minimal adverse effects
  - most commonly used is propofol or ketamine
  - a continuous propofol infusion may also be used for the maintenance phase of GA

**Table 8. Intravenous Induction Agents**

**Solubility of Volatile Anesthetics in Blood**

- Least Soluble to Most Soluble:
  - Nitrous oxide < desflurane < sevoflurane < isoflurane < halothane

**Volatile Inhalational Agents**
- examples include sevoflurane, desflurane, isoflurane, enflurane, halothane, and nitrous oxide

*As of 2011, Thipental has been discontinued from production for North America*

<td></td>
<td></td>
</tr>
</tbody>
</table>

*Properties and Adverse Effects of N\textsubscript{2}O

Due to its high MAC, nitrous oxide is combined with other anesthetic gases to obtain surgical anesthesia. A MAC of 104% is possible in a pressurized chamber only.

Second Gas Effect

Expansion of closed spaces: closed spaces such as a pneumothorax, the middle ear, bowel lumen and ETT cuff will markedly enlarge if N2O is administered.

Diffusion hypoxia: during anesthesia, the washout of N2O from body stores into alveoli can dilute the alveolar [O2], creating a hypoxic mixture if the original [O2] is low.

**Coronary steal: isoflurane causes small vessel dilation which may compromise blood flow to areas of the heart with fixed perfusion (e.g. stents, atherosclerosis).”

**MAC (Minimum Alveolar Concentration)**

- the alveolar concentration of a volatile anesthetic at one atmosphere (atm) of pressure that will prevent movement in 50% of patients in response to a surgical stimulus (e.g. abdominal incision).
- potency of inhalational agents is compared using MAC.
- MAC of halogenated volatile anesthetics decrease by approximately 6% per additional decade of age in adults.
- 1.2-1.3 times MAC will often ablate response to stimuli in the general population.
- MAC values are roughly additive when mixing N2O with another volatile agent; however, this only applies to movement, not other effects such as BP changes (e.g. 0.5 MAC of a potent agent + 0.5 MAC of N2O = 1 MAC of potent agent).
- MAC-intubation: the MAC of anesthetic that will inhibit movement and coughing during endotracheal intubation, generally 1.3 MAC.
- MAC-block adrenergic response (MAC-BAR): the MAC necessary to blunt the sympathetic response to noxious stimuli, generally 1.5 MAC.
- MAC-awake: the MAC of a given volatile anesthetic at which a patient will open their eyes to command, generally 0.3-0.4 of the usual MAC.

**Muscle Relaxants and Reversing Agents**

Factors increasing MAC: chronic alcohol use, hyperthyroidism, hyperthermia, stimulant (amphetamines), young age.

Factors decreasing MAC: acute alcohol intoxication, hypothermia, sedating drugs, advanced age, drugs (opioids, benzodiazepines).

Figure 11. Review of anatomy and physiology of the neuromuscular junction (NMJ)
Muscle Relaxants
- two types of muscle relaxants
  1. depolarizing muscle relaxants: succinylcholine (SCh)
  2. non-depolarizing muscle relaxants: rocuronium, mivacurium, vecuronium, cistracurium, pancuronium
- block nicotinic cholinergic receptors in NMJ
- provides skeletal muscle paralysis, including the diaphragm, but spares involuntary muscles such as the heart and smooth muscle
- never use muscle relaxants without adequate preparation and equipment to maintain airway and ventilation
- muscle relaxation produces the following desired effects:
  1. facilitates intubation
  2. assists with mechanical ventilation
  3. prevents muscle stretch reflex and decreases muscle tone
  4. allows access to the surgical field (intracavitary surgery)
- nerve stimulator (i.e. train of four) is used intraoperatively to assess the degree of nerve block; no twitch response seen with complete neuromuscular blockade

Table 10. Depolarizing Muscle Relaxants (Non-Competitive): Succinylcholine (SCh)

<table>
<thead>
<tr>
<th>Mechanism of Action</th>
<th>Mimics ACh and binds to ACh receptors causing prolonged depolarization; initial fasciculation may be seen, followed by temporary paralysis secondary to blocked ACh receptors by SCh</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intubating Dose (mg/kg)</td>
<td>1-1.5</td>
</tr>
<tr>
<td>Onset</td>
<td>30-60 s – rapid (fastest of all muscle relaxants)</td>
</tr>
<tr>
<td>Duration</td>
<td>3-5 min – short (no reversing agent for SCh)</td>
</tr>
<tr>
<td>Metabolism</td>
<td>SCh is hydrolyzed by plasma cholinesterase (pseudocholinesterase), found only in plasma and not at the NMJ</td>
</tr>
<tr>
<td>Indications</td>
<td>Assist intubation, Increased risk of aspiration (need rapid paralysis and airway control (e.g. full stomach), hiatus hernia, obesity, pregnancy, trauma), Short procedures, Electroconvulsive therapy (ECT), Laryngospasm</td>
</tr>
</tbody>
</table>
| Side Effects        | 1. SCh also stimulates muscarinic cholinergic autonomic receptors (in addition to nicotinic receptors; may cause bradycardia, dysrhythmias, sinus arrest, increased secretions of salivary glands (especially in children)  
  2. Hyperkalemia  
  Disruption of motor nerve activity causes proliferation of extrajunctional (outside NMJ) cholinergic receptors  
  Depolarization of an increased number of receptors by SCh may lead to massive release of potassium out of muscle cells  
  Patients at risk  
  3rd degree burns 24 h-6 mo after injury  
  Traumatic paralysis or neuromuscular diseases (e.g. muscular dystrophy)  
  Severe intra-abdominal infections  
  Severe closed head injury  
  Upper motor neuron lesions  
  3. Can trigger MH (see Malignant Hyperthermia, A28)  
  4. Increased ICP/intracocular pressure/intragastric pressure (no increased risk of aspiration if competent lower esophageal sphincter)  
  5. Fasciculations, post-operative myalgia – may be minimized if small dose of non-depolarizing agent given before SCh administration |
| Contraindications   | Absolute Known hypersensitivity or allergy, positive history of malignant hyperthermia, myotonia (m. congenita, m. dystrophica, paramyotonia congenital), high risk for hyperkalemic response  
  Relative Known history of plasma cholinesterase deficiency, myasthenia gravis, myasthenic syndrome, familial periodic paralysis, open eye injury |

Reversing Agents
- sugammadex is a selective relaxant binding agent
- neostigmine, pyridostigmine, edrophonium are acetylcholinesterase inhibitors
- administer reversal agents when there has been some recovery of blockade (i.e. muscle twitch)
- can only reverse the effect of non-depolarizing muscle relaxants
- anticholinergic agents (e.g. atropine, glycopyrrolate) are simultaneously administered to minimize muscarinic effect of reversal agents (i.e. bradycardia, salivation, increased peristalsis, and bronchoconstriction)

*Atropine and glycopyrrolate are anticholinergic agents administered to minimize muscarinic effects of reversal agents

Analgesia
- options include opioids (e.g. morphine, fentanyl, hydromorphone), NSAIDS, acetaminophen, ketamine, gabapentin, local, and regional anesthetic (see Table 15, A25)
Maintenance

- general anesthesia is maintained using volatile inhalation agents and/or IV agents (i.e. propofol infusion)
- analgesia (usually IV opioids) and muscle relaxants are also given as needed

Extubation

- criteria: patient must no longer have intubation requirements
  - patency: airway must be patent
  - protection: airway reflexes intact
  - patient must be oxygenating and ventilating spontaneously
- general guidelines
  - ensure patient has normal neuromuscular function (peripheral nerve stimulator monitoring) and hemodynamic status
  - ensure patient is breathing spontaneously with adequate rate and tidal volume
  - allow ventilation (spontaneous or controlled) with 100% O₂ for 3-5 min
  - suction secretions from pharynx, deflate cuff, remove ETT on inspiration (vocal cords abducted)
  - ensure patient is breathing adequately after extubation
  - ensure face mask for O₂ delivery available
  - proper positioning of patient during transfer to recovery room (supine, head elevated)

Complications of Extubation

- early extubation: aspiration, laryngospasm
- late extubation: transient vocal cord incompetence, edema (glottic, subglottic), pharyngitis, tracheitis

Laryngospasm

- defined as forceful involuntary spasm of laryngeal muscles caused by stimulation of superior laryngeal nerve (by oropharyngeal secretions, blood, extubation)
- causes partial or total airway obstruction
- more likely to occur in semi-conscious patients
- prevention: extubate while patient is still deeply under anesthesia or fully awake
- treatment: apply sustained positive pressure with bag-mask ventilation with 100% O₂, low-dose propofol (0.5-1.0 mg/kg) optional, low-dose succinylcholine (approximately 0.25 mg/kg) and reintubate if hypoxia develops

Regional Anesthesia

- local anesthetic agent (LA) applied around a peripheral nerve at any point along the length of the nerve (from spinal cord up to, but not including, the nerve endings) for the purpose of reducing or preventing impulse transmission
- no CNS depression (unless overdose of local anesthetic); patient remains conscious
- regional anesthetic techniques categorized as follows:
  - epidural and spinal anesthesia (neuraxial anesthesia)
  - peripheral nerve blocks
  - IV regional anesthesia (e.g. Bier block)

Patient Preparation

- sedation and/or anxiolysis may be indicated before block
- monitoring should be as extensive as for general anesthesia

Epidural and Spinal Anesthesia

- most common for surgeries performed below level of umbilicus but can be extended to any level (useful in thoracic, abdominal and lower extremity surgeries). Typically placed in thoracic or lumbar spine

Anatomy of Spinal/Epidural Area

- spinal cord extends to L2; dural sac to S2 in adults
- nerve roots (cauda equina) from L2 to S2
- needle inserted below L2 should not encounter cord, thus L3-L4, L4-L5 interspace commonly used
- structures penetrated (outside to inside)
  - skin
  - subcutaneous fat
  - supraspinous ligament
  - interspinous ligament
  - ligamentum flavum (last layer before epidural space)
  - dura + arachnoid for spinal anesthesia

Benefits of Regional Anesthesia

- Reduced perioperative pulmonary complications
- Reduced perioperative analgesia requirements
- Decreased PONV
- Reduced perioperative blood loss
- Ability to monitor CNS status during procedure
- Improved perfusion
- Lower incidence of VTE
- Shorter recovery and improved rehabilitation
- Pain blockade with preserved motor function

Landmarking Epidural/Spinal Anesthesia

- Spinous processes should be maximally flexed
- L4 spinous processes found between iliac crests
- T7 landmark at the tip of the scapula

Classic Presentation of Dural Puncture Headache

- Onset 6 h-3 d after dural puncture
- Postural component (worse when sitting)
- Occipital or frontal localization
- ± tinnitus, diplopia
Table 13. Epidural vs. Spinal Anesthesia

<table>
<thead>
<tr>
<th></th>
<th>Epidural</th>
<th>Spinal</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Deposition Site</strong></td>
<td>LA injected in epidural space (space between ligamentum flavum and dura). Initial blockade is at the spinal roots followed by some degree of spinal cord anesthesia as LA diffuses into the subarachnoid space through the dura.</td>
<td>LA injected into subarachnoid space in the dural sac surrounding the spinal cord and nerve roots.</td>
</tr>
<tr>
<td><strong>Onset</strong></td>
<td>Significant blockade requires 10-15 min; Slower onset of side effects.</td>
<td>Rapid blockade (onset in 2-5 min).</td>
</tr>
<tr>
<td><strong>Effectiveness</strong></td>
<td>Effectiveness of blockade can be variable.</td>
<td>Very effective blockade.</td>
</tr>
<tr>
<td><strong>Difficulty</strong></td>
<td>Technically more difficult; greater failure rate.</td>
<td>Easier to perform due to visual confirmation of CSF flow.</td>
</tr>
<tr>
<td><strong>Patient Positioning</strong></td>
<td>Position of patient not as important; specific gravity not an issue.</td>
<td>Hyperbaric LA solution – position of patient important.</td>
</tr>
<tr>
<td><strong>Specific Gravity/Spread</strong></td>
<td>Epidural injections spread throughout the potential space; specific gravity of solution does not affect spread.</td>
<td>LA solution may be made hyperbaric (of greater specific gravity than the CSF by mixing with 10% dextrose, thus increasing spread of LA to the dependent (low) areas of the subarachnoid space).</td>
</tr>
<tr>
<td><strong>Dosage</strong></td>
<td>Larger volume/dose of LA (usually &gt; toxic IV dose).</td>
<td>Smaller dose of LA required (usually &lt; toxic IV dose).</td>
</tr>
<tr>
<td><strong>Continuous Infusion</strong></td>
<td>Use of catheter allows for continuous infusion or repeat injections.</td>
<td>None.</td>
</tr>
<tr>
<td><strong>Complications</strong></td>
<td>Failure of technique; Hypotension; Bradycardia if cardiac sympathetics blocked (only if ~T2-4 block), e.g., “high spinal”; Epidural or subarachnoid hematoma; Accidental subarachnoid injection can produce spinal anesthesia (and any of the above complications); Systemic toxicity of LA (accidental intravenous); Catheter complications (shearing, kinking, vascular or subarachnoid placement); Infection; Dural puncture</td>
<td>Failure of technique; Hypotension; Bradycardia if cardiac sympathetics blocked (only if ~T2-4 block), e.g., “high spinal”; Epidural or subarachnoid hematoma; Post-spinal headache (CSF leak); Transient paresthesias; Spinal cord trauma; Infection.</td>
</tr>
</tbody>
</table>

**Combined Spinal-Epidural**
Combines the benefits of rapid, reliable, intense blockade of spinal anesthesia together with the flexibility of an epidural catheter.

**Contraindications to Spinal/Epidural Anesthesia**
- absolute contraindications
  - lack of resuscitative drugs/equipment
  - patient refusal
  - allergy to local anesthetic
  - infection at puncture site or underlying tissues
  - coagulopathies/bleeding diathesis
  - raised ICP
  - sepsis/bacteremia
  - severe hypovolemia
  - cardiac lesion with fixed output states (severe mitral/aortic stenosis)
  - lack of IV access
• relative contraindications
  • pre-existing neurological disease (demyelinating lesions)
  • previous spinal surgery, severe spinal deformity
  • prolonged surgery
  • major blood loss or maneuvers that can compromise reaction

Peripheral Nerve Blocks
• deposition of LA around the target nerve or plexus
• ultrasound guidance and peripheral nerve stimulation (needle will stimulate target nerve/plexus) may be used to guide needle to target nerve while avoiding neural trauma or intraneural injection
• most major nerves or nerve plexi can be targeted (brachial plexus block, femoral nerve block, sciatic nerve block, etc.)
• performed with standard monitors
• approximately 2-4 per 10,000 risk of late neurologic injury
• resuscitation equipment must be available

Contraindications to Peripheral Nerve Blockade
• absolute contraindications
  • allergy to LA
  • patient refusal
• relative contraindications
  • certain types of pre-existing neurological dysfunction (e.g. ALS, MS, diabetic neuropathy)
  • local infection at block site
  • bleeding disorder

Local Anesthesia

Local Anesthetic Agents
• see Table 14, A22, for list of LA agents

Definition and Mode of Action
• LA are drugs that block the generation and propagation of impulses in excitable tissues: nerves, skeletal muscle, cardiac muscle, brain
• LA bind to receptors on the cytosolic side of the Na+ channel, inhibiting Na+ flux and thus blocking impulse conduction
• different types of nerve fibres undergo blockade at different rates

Absorption, Distribution, Metabolism
• LA readily crosses the blood-brain barrier (BBB) once absorbed into the bloodstream
• ester-type LA (e.g. procaine, tetracaine) are broken down by plasma and hepatic esterases; metabolites excreted via kidneys
• amide-type LA (lidocaine, bupivacaine) are broken down by hepatic mixed-function oxidases (P450 system); metabolites excreted via kidneys

Selection of LA
• choice of LA depends on:
  • onset of action: influenced by pKa (the lower the pKa, the higher the concentration of the base form of the LA, and the faster the onset of action)
  • duration of desired effects: influenced by protein binding (longer duration of action when protein binding of LA is strong)
  • potency: influenced by lipid solubility (agents with high lipid solubility penetrate the nerve membrane more easily)
  • unique needs (e.g. sensory blockade with relative preservation of motor function by bupivacaine at low doses)
  • potential for toxicity

Systemic Toxicity

- see Table 14, A22 for maximum doses, potency, and duration of action for common LA agents
- occurs by accidental intravascular injection, LA overdose, or unexpectedly rapid absorption

CNS Effects

- CNS effects first appear to be excitatory due to initial block of inhibitory fibres, then subsequent block of excitatory fibres
- effects in order of appearance
  - numbness of tongue, perioral tingling, metallic taste
  - disorientation, drowsiness
  - tinnitus
  - visual disturbances
  - muscle twitching, tremors
  - unconsciousness
  - convulsions, seizures
  - generalized CNS depression, coma, respiratory arrest

CVS Effects

- vasodilation, hypotension
- decreased myocardial contractility
- dose-dependent delay in cardiac impulse transmission
  - prolonged PR, QRS intervals
  - sinus bradycardia
- CVS collapse

Treatment of Systemic Toxicity

- early recognition of signs; get help
- 100% O₂, manage ABCs
- diazepam or other anticonvulsant to prevent potential onset of seizures
- manage arrhythmias
- Intralipid® 20% to bind local anesthetic in circulation

Local Infiltration and Hematoma Blocks

Local Infiltration

- injection of tissue with LA, producing a lack of sensation in the infiltrated area due to LA acting on nerves
- suitable for small incisions, suturing, excising small lesions
- can use fairly large volumes of dilute LA to infiltrate a large area
- low concentrations of epinephrine (1:100,000–1:200,000) cause vasoconstriction, thus reducing bleeding and prolonging the effects of LA by reducing systemic absorption

Fracture Hematoma Block

- special type of local infiltration for pain control during manipulation of certain fractures
- hematoma created by fracture is infiltrated with LA to anesthetize surrounding tissues
- sensory blockade may only be partial
- no muscle relaxation

Topical Anesthetics

- various preparations of local anesthetics available for topical use, may be a mixture of agents (EMLA cream is a combination of 2.5% lidocaine and prilocaine)
- must be able to penetrate the skin or mucous membrane

Post-Operative Care

- pain management should be continuous from OR to post-anesthetic care unit (PACU) to hospital ward and home

Common Post-Operative Anesthetic Complications

Uncontrolled/Poorly Controlled Pain

Nausea and Vomiting

- hypotension and bradycardia must be ruled out
- pain and surgical manipulation also cause nausea
- often treated with dimenhydrinate (Gravol®), metoclopramide (Maxeran®; not with bowel obstruction), prochlorperazine (Stemetil®), ondansetron (Zofran®), granisetron (Kytril®)
Pain Management

Confusion and Agitation
- ABCs first – confusion or agitation can be caused by airway obstruction, hypercapnea, hypoxemia
- neurologic status (Glasgow Coma Scale, pupils), residual paralysis from anesthetic
- pain, distended bowel/bladder
- fear/anxiety/separation from caregivers, language barriers
- metabolic disturbance (hypoglycemia, hypercalcemia, hyponatremia – especially post-TURP)
- intracranial cause (stroke, raised ICP)
- drug effect (ketamine, anticholinergics, serotonin)
- elderly patients are more susceptible to post-operative delirium

Respiratory Complications
- susceptible to aspiration of gastric contents due to PONV and unreliable airway reflexes
- airway obstruction (secondary to reduced muscle tone from residual anesthetic, soft tissue trauma and edema, or pooled secretions) may lead to inadequate ventilation, hypoxemia, and hypercapnia
- airway obstruction can often be relieved with head tilt, jaw elevation, and anterior displacement of the mandible. If the obstruction is not reversible, a nasal or oral airway may be used

Hypotension
- must be identified and treated quickly to prevent inadequate perfusion and ischemic damage
- reduced cardiac output (hypovolemia, most common cause) and/or peripheral vasodilation (residual anesthetic agent)
- first step in treatment is usually the administration of fluids ± inotropic agents

Hypertension
- pain, hypercapnia, hypoxemia, increased intravascular fluid volume, and sympathomimetic drugs can cause hypertension
- IV nitroglycerin, hydralazine, calcium channel blockers or β-blocking drugs (e.g. esmolol and metoprolol) can be used to treat hypertension

Definitions
- pain: perception of nociception, which occurs in the brain
- nociception: detection, transduction, and transmission of noxious stimuli

Pain Classifications
- temporal: acute vs. chronic
- mechanism: nociceptive vs. neuropathic

Acute Pain
- pain of short duration (<6 wk) usually associated with surgery, trauma, or acute illness; often associated with inflammation
- usually limited to the area of damage/trauma and resolves with healing

Figure 15. Acute pain mechanism

Risk Factors for Post-Operative Nausea and Vomiting (PONV)
- Young age
- Female
- History of PONV
- Non-smoker
- Type of surgery: ophtho, ENT, abdo/pelvic, plastics
- Type of anesthetic: N₂O, opioids, volatile agents

Dexamethasone versus Standard Treatment for Postoperative Nausea and Vomiting in Gastrointestinal Surgery: Randomised Controlled Trial (DREAMS Trial)

Objectives: Whether preoperative dexamethasone reduces postoperative vomiting in patients undergoing elective bowel surgery and whether it is associated with other measurable benefits during recovery from surgery.

Method: Pragmatic two arm parallel group randomised trial with blinded postoperative care and outcome assessment.

Results: Patients receiving additional 8 mg of IV dexamethasone at induction is associated with lower rates of vomiting within 24 hours of surgery (NNT=13) and reduced need for antiemetics up to 72h (NNT=8) vs. standard of care.

Conclusions: A single dose of dexamethasone at induction of anesthesia significantly reduces incidence of PONV and need for rescue antiemetics post-operatively with no increase in adverse events.

Figure 16. WHO analgesia ladder
Pharmacological Management of Acute Pain

- ask the patient to rate the pain out of 10, or use visual analog scale, to determine severity
- pharmacological treatment guided by WHO analgesia ladder
- patient controlled analgesia (PCA)
  - involves the use of computerized pumps that can deliver a constant infusion and bolus breakthrough doses of parenterally-administered opioid analgesics
  - limited by lockout intervals
  - most commonly used agents: morphine and hydromorphone
  - see Table 17, A26 for suggested infusion rate, PCA dose and lockout intervals

</tr>
</tbody>
</table>

#### Common Side Effects of Opioids

- N/V
- Constipation
- Sedation
- Pruritus
- Abdominal pain
- Urinary retention
- Respiratory depression

When prescribing opioids, consider:

- Breakthrough dose
- Anti-emetics
- Laxative

#### PCA Parameters

- Loading dose
- Bolus dose
- Lockout interval
- Continuous infusion (optional)
- Maximum 4 h dose limit

#### Advantages of PCA

- Improved patient satisfaction
- Fewer side effects
- Accommodates patient variability
- Accommodates changes in opioid requirements

#### Patient Controlled Opioid Analgesia versus Non-Patient Controlled Opioid Analgesia for Postoperative Pain

Cochrane DB Syst Rev 2019:CD003248

**Purpose**: To evaluate the efficacy of patient controlled analgesia (PCA) versus non-patient controlled opioid analgesia of as-needed opioid analgesia for postoperative pain relief

**Methods**: Meta-analyses of RCTs comparing PCA vs. conventional administration of opioid analgesia. Assessment employed a visual analog scale (VAS) for pain intensity along with overall analgesic consumption, patient satisfaction, length of stay, and adverse side effects.

**Results**: 49 studies with a total of 1725 patients receiving PCA and 1687 patients assigned to a control group. PCA had a lower VAS pain intensity score vs. non-patient controlled analgesia over most time intervals in the first 48h. PCA was associated with higher patient satisfaction and consumed higher amounts of opioids than controls. PCA was also associated with higher incidence of pruritus but not other adverse events.

**Conclusions**: Moderate to low quality evidence that PCA is an efficacious alternative to non-patient controlled systemic analgesia for postoperative pain control.

</tr>
</thead>
<tbody>
<tr>
<td>Remifentanil</td>
<td>100 µg IV</td>
<td>0.5-1.5 µg/kg IV</td>
<td>Rapid (1-3 min)</td>
<td>Ultra short (&lt;10 min)</td>
<td>Only use during induction and maintenance of anesthesia</td>
</tr>
<tr>
<td>Methadone (opioid agonist)</td>
<td>Morphine to methadone conversion is variable based on patient's morphine dose. Ranges from 1/4 to 1/20</td>
<td>15-40 mg/d in divided doses</td>
<td>Rapid (8 min)</td>
<td>15-50 (34h average)</td>
<td>Can only be prescribed by federally/ provincially licensed physicians Acts through both NMDA and mu receptors Challenges due to variable equianalgesic dose and half-life After titration, accumulates in tissue for once/twice daily dosing Metabolized by CYP3A4 Caution with high doses, may cause QT prolongation, baseline ECG required</td>
</tr>
<tr>
<td>Buprenorphine (opioid agonist antagonist)</td>
<td>Varies depending on route of administration (pill/film, transdermal)</td>
<td>Film: 2 mg up to max of 24 mg</td>
<td>Moderate (30 min)</td>
<td>6-8 h</td>
<td>For moderate to severe chronic pain and opioid addiction Ceiling effect for respiratory depression but not analgesia High affinity to mu-opioid receptors, very resistant to reversal with opioid antagonists</td>
</tr>
</tbody>
</table>

In general, parenteral route is 2-3x more potent than oral.

Opoid Antagonists (naloxone, naltrexone)
- indication: opioid overdose (manifests primarily at CNS, e.g. respiratory depression)
- mechanism of action: competitively inhibit opioid receptors, predominantly µ receptors
  - naloxone is short-acting (t1/2 = 1 h); effects of narcotic may return when naloxone wears off; therefore, the patient must be observed closely following its administration
  - naltrexone is longer-acting (t1/2 = 10 h); less likely to see return of opioid effects
- side effects: relative overdose of naloxone may cause nausea, agitation, sweating, tachycardia, hypertension, re-emergence of pain, pulmonary edema, seizures (essentially opioid withdrawal)

Neuropathic Pain
- see Neurology, N41

Chronic Pain
- chronic pain: greater than 3 mo, or recurrent pain that occurs at least 3 times throughout 3 mo period
- pain of duration or intensity that persists beyond normal tissue healing and adversely affects functioning
- in the perioperative period, consider continuing regular long-acting analgesics and augmenting with regional techniques, adjuvants, additional opioid analgesia and non-pharmacological techniques

Central Sensitization
- central sensitization: hyperalgesia (increased sensitivity to pain) as a result of central nervous system mechanisms
- may have nociceptive and neuropathic components; dysregulation of analgesic pathways implicated
- plays a role in fibromyalgia

Chronic Post-Surgical Pain
- chronic post-surgical pain (CPSP): pain that develops after surgery and persists for at least 2 mo
- primary predictor of CPSP is history of chronic pain; other risk factors include female gender, surgical procedure/approach, poor social supports, catastrophizing behaviour
Obstetrical Anesthesia

Anesthesia Considerations in Pregnancy

- **airway**
  - possible difficult airway as tissues becomes edematous and friable especially in labour
- **respiratory**
  - decreased FRC and increased O₂ consumption cause more rapid desaturation during apnea
- **cardiovascular system**
  - increased blood volume > increased RBC mass results in mild anemia
  - decreased SVR proportionately greater than increased CO results in decreased BP
  - prone to decreased BP due to aortocaval compression (supine hypotensive syndrome) – therefore for surgery, a pregnant patient is positioned in left uterine displacement (approximately 15ºC) using a wedge under her right flank
- **central nervous system**
  - decreased MAC due to hormonal effects
  - increased block height due to engorged epidural veins
- **gastrointestinal system**
  - delayed gastric emptying
  - increased volume and acidity of gastric fluid
  - decreased LES tone
  - increased abdominal pressure
  - combined, these lead to an increased risk of aspiration – therefore for surgery, a pregnant patient is given sodium citrate 30 cc PO immediately before surgery to neutralize gastric acidity

Options for Analgesia during Labour

- **psychoprophylaxis** – Lamaze method
  - patterns of breathing and focused attention on fixed object
- **systemic medication**
  - easy to administer, but risk of maternal or neonatal respiratory depression
  - opioids most commonly used if delivery is not expected within 4 h; fentanyl can be considered
- **inhalational analgesia**
  - easy to administer, makes uterine contractions more tolerable, but does not relieve pain completely
  - 50% nitrous oxide is insufficient alone but good safety profile for mother + child
- **neuraxial analgesia**
  - provides excellent analgesia with minimal depressant effects
  - hypotension is the most common complication
  - maternal BP monitored q2-5min for 15-20 min after initiation and regularly thereafter
  - epidural usually given as it preferentially blocks sensation, leaving motor function intact

Options for Caesarean Section

- **neuraxial:** spinal or epidural
- **general:** used if contraindications or time precludes regional blockade (see *Regional Anesthesia, Epidural and Spinal Anesthesia*, A20)

Pediatric Anesthesia

Respiratory System

- in comparison to adults, anatomical differences in infants include:
  - large head, short trachea/neck, large tongue, larynx positioned more superior and anterior, adenoids, and tonsils
  - narrow nasal passages (obligate nasal breathers until 5 mo)
  - narrowest part of airway at the level of the cricoid vs. glottis in adults
  - epiglottis is longer, U shaped and angled at 45º; carina is wider and is at the level of T2 (T4 in adults)
- physiologic differences include:
  - faster RR, immature respiratory centres which are depressed by hypoxia/hypercapnea (airway closure occurs in the neonate at the end of expiration)
  - less oxygen reserve during apnea – decreased total lung volume, vital and functional reserve capacity together with higher metabolic needs
  - greater V/Q mismatch – lower lung compliance due to immature alveoli (mature at 8 yr)
  - greater work of breathing – greater chest wall compliance, weaker intercostals/diaphragm, and higher resistance to airflow

Cardiovascular System

- blood volume at birth is approximately 80 mL/kg; transfusion should be started if >10% of blood volume is lost
- children have a high HR and low BP
- CO is dependent on HR, not stroke volume because of low heart wall compliance; therefore, bradycardia severe compromise in CO
Uncommon Complications

Temperature Regulation
- vulnerable to hypothermia
- minimize heat loss by use of warming blankets, covering the infant’s head, humidification of inspired gases, and warming of infused solutions

Central Nervous System
- MAC of halothane is increased compared to the adult (0.75% adult, 1.2% infant, 0.87% neonate)
- NMJ is immature for the first 4 wk of life and thus there is an increased sensitivity to non-depolarizing relaxants
- parasympathetics mature at birth, sympathetics mature at 4-6 mo; thus, there is an autonomic imbalance
- infant brain is 12% of body weight and receives 34% of CO (adult: 2% body weight and 14% CO)

Glucose Maintenance
- infants <1 yr can become seriously hypoglycemic during pre-operative fasting and post-operatively if feeding is not recommenced as soon as possible
- after 1 yr, children are able to maintain normal glucose homeostasis in excess of 8 h

Pharmacology
- higher dose requirements because of higher TBW (75% vs. 60% in adults) and greater volume of distribution
- barbiturates/opioids more potent due to greater permeability of BBB
- muscle relaxants
  - non-depolarizing
  - immature NMJ, variable response
  - depolarizing
    - must pre-treat with atropine or may experience profound bradycardia and/or sinus node arrest due to PNS > SNS (also dries oral secretions)
    - more susceptible to arrhythmias, hyperkalemia, rhabdomyolysis, myoglobinemia, masseter spasm and malignant hyperthermia

Uncommon Complications

Malignant Hyperthermia
- hypermetabolic disorder of skeletal muscle
- due to an uncontrolled increase in intracellular Ca²⁺ (because of an anomaly of the ryanodine receptor which regulates Ca²⁺ channel in the sarcoplasmic reticulum of skeletal muscle)
- autosomal dominant inheritance
- incidence of 1-5 in 100,000, may be associated with skeletal muscle abnormalities such as dystrophy or myopathy
- anesthetic drugs triggering MH include:
  - all inhalational agents except nitrous oxide
  - depolarizing muscle relaxants: SCh

Clinical Picture
- onset: immediate or hours after contact with trigger agent
  - increased oxygen consumption
  - increased ETCO₂ on capnograph
  - tachycardia/dysrhythmia
  - tachypnea/cyanosis
  - diaphoresis
  - hypertension
  - increased temperature (late sign)
- muscular symptoms
  - trismus (masseter spasm) common but not specific for MH (occurs in 1% of children given SCh with halothane anesthesia)
  - tender, swollen muscles due to rhabdomyolysis
  - trunk or total body rigidity

Complications
- coma
- DIC
- rhabdomyolysis
- myoglobinuric renal failure/hepatic dysfunction
- electrolyte abnormalities (e.g. hyperkalemia) and secondary arrhythmias
- ARDS
- pulmonary edema
- can be fatal if untreated

Signs of Malignant Hyperthermia
- Unexplained rise in ETCO₂
- Increase in minute ventilation
- Tachycardia
- Rigidity
- Hyperthermia (late sign)
**Prevention**
- suspect MH in patients with a family history of problems/death with anesthetic
- avoid all trigger medications, use vapor-free equipment, use regional anesthesia if possible
- central body temp and ETCO₂ monitoring

**Malignant Hyperthermia Management**
(Based on Malignant Hyperthermia Association of the U.S. [MHAUS] Guidelines, 2008)
1. notify surgeon, discontinue volatile agents and succinylcholine, hyperventilate with 100% oxygen at flows of 10 L/min or more, halt the procedure as soon as possible
2. dantrolene 2.5 mg/kg IV, through large-bore IV if possible
   - repeat until there is control of signs of MH; up to 30 mg/kg as necessary
3. bicarbonate 1-2 mEq/kg if blood gas values are not available for metabolic acidosis
4. cool patients with core temperature >39°C
   - lavage open body cavities, stomach, bladder, rectum; apply ice to surface; infuse cold saline IV
   - stop cooling if temperature is <38°C to prevent drift to <36°C
5. dysrhythmias usually respond to treatment of acidosis and hyperkalemia
   - use standard drug therapy except Ca²⁺ channel blockers as they may cause hyperkalemia and cardiac arrest in presence of dantrolene
6. hyperkalemia
   - treat with hyperventilation, bicarbonate, glucose/insulin, calcium
   - bicarbonate 1-2 mEq/kg IV, calcium chloride 10 mg/kg or calcium gluconate 10-50 mg/kg for life-threatening hyperkalemia and check glucose levels hourly
7. follow ETCO₂, electrolytes, blood gases, creatine kinase (CK), core temperature, urine output/colour with Foley catheter, coagulation studies
   - if CK and/or potassium rises persistently or urine output falls to <0.5 mL/kg/h, induce diuresis to >1 mL/kg/h urine to avoid myoglobinuric renal failure
8. maintain anesthesia with benzodiazepines, opioids, and propofol
9. transfer to ICU bed

**Abnormal Pseudocholinesterase**
- pseudocholinesterase hydrolyzes SCh and mivacurium
- individuals with abnormal pseudocholinesterase will have prolonged muscular blockade
- SCh and mivacurium are contraindicated in those with abnormal pseudocholinesterase
- if SCh or mivacurium are given accidentally, treat with mechanical ventilation until function returns to normal (do not use cholinesterase inhibitors as it will cause rebound neuromuscular blockade once cholinesterase inhibitor effect is terminated)
Figure 18. Difficult tracheal intubation encountered in the unconscious patient

**Difficult Tracheal Intubation**

**Figure 19. Anticipated difficult tracheal intubation**

- IV = intravenous; RSI = rapid sequence induction/intubation; SGD = supraglottic device

Advanced Cardiac Life Support Guidelines

Figure 20. Adult cardiac arrest algorithm
### Adult Tachycardia (With Pulse)

1. **Assess appropriateness for clinical condition**
   - Heart rate typically ≥150/min if tachyarrhythmia

2. **Identify and treat underlying cause**
   - Maintain patent airway; assist breathing as necessary
   - Oxygen (if hypoxicemic)
   - Cardiac monitor to identify rhythm; monitor blood pressure and oximetry

3. **Persistent tachyarrhythmia causing:**
   - Hypotension?
   - Acutely altered mental status?
   - Signs of shock?
   - Ischemic chest discomfort?
   - Acute heart failure?

4. **Synchronized cardioversion**
   - Consider sedation
   - If regular narrow complex, consider adenosine

5. **Wide QRS?**
   - ≥0.12 second

   5a. **Yes**
      - IV access and 12-lead ECG if available
      - Consider adenosine only if regular and monomorphic
      - Consider antiarrhythmic infusion
      - Consider expert consultation

   5b. **No**
      - IV access and 12-lead ECG if available
      - Vagal maneuvers
      - Adenosine (if regular)
      - β-Blockers or calcium channel blocker
      - Consider expert consultation

6. **Consider:**
   - Expert consultation
   - Transvenous pacing

---

### Adult Bradycardia (With Pulse)

1. **Assess appropriateness for clinical condition**
   - Heart rate typically <50/min if bradycardia

2. **Identify and treat underlying cause**
   - Maintain patent airway; assist breathing as necessary
   - Oxygen (if hypoxicemic)
   - Cardiac monitor to identify rhythm; monitor blood pressure and oximetry
   - IV access
   - 12-Lead ECG if available; do not delay therapy

3. **Persistent bradycardia causing:**
   - Hypotension?
   - Acutely altered mental status?
   - Signs of shock?
   - Ischemic chest discomfort?
   - Acute heart failure?

4. **Monitor and observe**
   - **Yes**
   - **No**

5. **Atropine**
   - If atropine ineffective:
     - Transcutaneous pacing OR
     - Dopamine infusion OR
     - Epinephrine infusion

6. **Consider:**
   - Expert consultation
   - Transvenous pacing

---

**Doses/Details**

**Synchronized Cardioversion**
- Initial recommended doses:
  - Narrow regular: 50-100 J
  - Narrow irregular: 120-200 J biphasic or 200 J monophasic
  - Wide regular: 100 J
  - Wide irregular: defibrillation dose (NOT synchronized)

**Adenosine IV Dose:**
- First dose: 6 mg rapid IV push; follow with NS flush
- Second dose: 12 mg if required

**Antiarrhythmic Infusions for Stable Wide-QRS Tachycardia**

**Procainamide IV Dose:**
- 20-50 mg/min until arrhythmia suppressed, hypotension ensues, QRS duration increases >50%, or maximum dose 17 mg/kg given
- Maintenance infusion: 1-4 mg/min
- Avoid if prolonged QT or CHF

**Amiodarone IV Dose:**
- First dose: 150 mg over 10 min
- Repeat as needed if VT recurs
- Follow by maintenance infusion of 1 mg/min for first 6 h

**Sotalol IV Dose:**
- 100 mg (1.5 mg/kg) over 5 min
- Avoid if prolonged QT

---

Basic Anatomy Review

Coronary Circulation

- conventional arterial supply to the heart arises from the right and left coronary arteries, which originate from the root of the aorta
  - right coronary artery (RCA):
    - acute marginal branches
    - atrioventricular (AV) nodal artery
    - posterior descending artery (PDA) = posterior interventricular artery (PIV)
  - left main coronary artery (LCA):
  - left anterior descending artery (LAD):
    - septal branches
    - diagonal branches
    - left circumflex artery (LCx):
    - obtuse marginal branches
  - dominance of circulation
    - determined by whether the RCA or the LCx supplies the PDA
    - right-dominant circulation: PDA and at least one posterolateral branch arise from RCA (80%)
    - left-dominant circulation: PDA and at least one posterolateral branch arise from LCx (15%)
    - balanced circulation: dual supply of posteroinferior LV from RCA and LCx (5%)
  - the sinoatrial (SA) node is supplied by the SA nodal artery, which may arise from the RCA (60%) or LCx (40%)
  - most venous blood from the heart drains into the RA through the coronary sinus, although a small amount drains through the Thebesian veins into all four chambers, contributing to the physiologic R-L shunt

Figure 1. Anatomy of the coronary arteries (right anterior oblique projection)
Cardiac Anatomy

- **layers of the heart**
  - endocardium, myocardium, epicardium, visceral pericardium, pericardial cavity, parietal pericardium

- **valves**
  - semilunar valves:
    - aortic valve, 3 valve leaflets: separates LV and ascending aorta
    - pulmonic valve, 3 valve leaflets: separates RV and main pulmonary artery (PA)

- atrioventricular valves: subvalvular apparatus present in the form of chordae tendinae and papillary muscles
  - tricuspid valve, 3 valve leaflets: separates RA and RV
  - mitral/bicuspid valve, 2 valve leaflets: separates LA and LV

- **conduction system**
  - SA node governs pacemaking control; the heart beat originates here
  - anterior-, middle-, and posterior-internal nodal tracts carry impulses in the right atrium and along Bachmann’s bundle in the left atrium
  - atrial impulses converge at the AV node
  - the AV node is the only conducting tract from the atria to the ventricles because of electrical isolation by the annulus fibrosis (except when accessory pathways are present)
    - AV node connects to the bundle of His, which divides into left and right bundle branches (LBB and RBB)
    - LBB further splits into anterior and posterior fascicles
    - RBB and fascicles of LBB give off Purkinje fibres which conduct impulses into the ventricular myocardium

### Features of Abnormal JVP Wave Formation
- Atrial fibrillation: absent a wave
- 3rd degree heart block: cannon a waves
- Tricuspid regurgitation: cv wave, elevated JVP
- Cardiac tamponade: x descent only, absent y descent
- Constrictive pericarditis: prominent y descent, Kussmaul’s sign (paradoxical increase in JVP with inspiration)
• cardiovascular innervation
  • sympathetic nerves
    • innervate the SA node, AV node, ventricular myocardium, and vasculature
    • SA node (β1) increased activity leads to increased heart rate via more frequent impulse from pacemaking cells (increased chronotropy - increased HR)
    • cardiac muscle (β1) fibres increase contractility (inotropy - leads to increased SV)
    • stimulation of β1- and β2-receptors in the skeletal and coronary circulation causes vasodilatation
  • parasympathetic nerves
    • innervate the SA node, AV node, and atrial myocardium but few vascular beds
    • at rest, vagal tone dominates the tonic sympathetic stimulation of the SA node and AV node resulting in slowing of pacemaker activity (leading to a heart rate at rest slower than the intrinsic heart rate) and conduction (i.e. reduced dromotropy – if only affecting AV node conduction)
  • parasympathetics have very little impact on total peripheral vascular resistance

Differential Diagnoses of Common Presentations

Note: bold text indicates most common, underlined text indicates life threatening condition

Chest Pain

• cardiac
  • MI, angina, myocarditis, and pericarditis/Dressler's syndrome
• pulmonary
  • PE, pneumothorax/hemothorax, tension pneumothorax, pneumonia, empyema, pulmonary neoplasm, bronchiectasis, pleuritis, and TB
• gastrointestinal
  • esophageal: GERD, esophageal rupture, spasm, esophagitis, ulceration, achalasia, neoplasm, and Mallory-Weiss syndrome
  • other structures: PUD, gastritis, pancreatitis, and biliary colic
• mediastinal
  • lymphoma, thymoma
• vascular
  • dissecting aortic aneurysm, aortic rupture
• surface structures
• costochondritis
• rib fracture
• skin (bruising, herpes zoster)
• breast
• anxiety/psychosomatic

Loss of Consciousness

1. Causes of true syncope (impaired cerebral perfusion)
  • inadequate circulating volume (bleeding, hypovolemia with orthostasis)
  • obstruction to blood flow
    • tamponade
    • pulmonary embolism
    • severe pulmonary hypertension
    • severe obstructive valve disease (mitral and aortic stenosis)
    • left ventricular outflow obstruction (HCM)
  • cerebrovascular events (e.g. CVA, TIA)
  • sudden loss of cardiac output
    • tachyarrhythmia, ventricular tachycardia, VF
    • severe bradycardia (AV block/AV dyssynchrony)
  • reflex mediated/reflex dysfunction
    • vasovagal (most common)
    • situational (micturition, cough, carotid hypersensitivity)
    • autonomic dysfunction (often associated with neurologic diseases)

2. Loss of consciousness NOT due to impaired cerebral perfusion
  • seizure
  • hypoglycemia
  • severe hypoxia or hypercarbia
  • psychiatric
  • adverse drug events (e.g. anti-hypertensives)

Local Edema

• venous or lymphatic obstruction
  • thrombophlebitis/deep vein thrombosis, venous insufficiency, chronic lymphangitis, lymphatic tumour infiltration, filariasis
• inflammation/infection
• trauma
Generalized Edema

- increased hydrostatic pressure/ fluid overload
  - heart failure, pregnancy, drugs (e.g., CCBs), iatrogenic (e.g., IV fluids)
- decreased oncotic pressure/ hypoalbuminemia
  - liver cirrhosis, nephrotic syndrome, malnutrition
- increased interstitial oncotic pressure
  - myxedema
- increased capillary permeability
  - severe sepsis
- hormonal
  - hypothyroidism, exogenous steroids, pregnancy, estrogens

Palpitations

- palpitations that are continuous rapid heart action:
  - conditions causing sinus tachycardia: endocrine (thyrotoxicosis, pheochromocytoma, and hypoglycemia), systemic (anemia, fever), drugs (stimulants and anticholinergics), and psychiatric (panic attacks)
  - conditions causing pathologic tachycardia: SVT (atrial tach, A fib, and A flutter) and re-entrant SVT, VT
- palpitations with irregular/ intermittent sensations e.g. PACs, PVCs

Dyspnea

- cardiovascular
  - due to elevated pulmonary venous pressure: acute MI, CHF/LV failure, aortic/mitral stenosis, aortic/mitral regurgitation, arrhythmia, cardiac tamponade, constrictive pericarditis, and left-sided obstructive lesions (e.g. left atrial myxoma)
- respiratory
  - airway disease
    - asthma, COPD exacerbation, and upper airway obstruction (anaphylaxis, foreign body, and mucus plugging)
  - parenchymal lung disease
    - ARDS, pneumonia, interstitial lung disease
  - pulmonary vascular disease
    - PE, pulmonary HTN, pulmonary vasculitis
  - pleural disease
    - pneumothorax, pleural effusion
- neuromuscular and chest wall disorders
  - C-spine injury
    - polymyositis, myasthenia gravis, Guillain-Barré syndrome, and kyphoscoliosis
- anxiety/ psychosomatic
- hematological/metabolic
  - anemia, acidosis, hypercapnia
- drugs and poisons
  - CNS depressants, carbon monoxide poisoning

Cardiac Diagnostic Tests

Electrocardiography Basics

Description

- a graphical representation (time vs. amplitude of electrical vector projection) of the heart’s electrical activity
- on the ECG graph
  - the horizontal axis represents time (at usual paper speed 25 mm/s)
    - 1 mm (1 small square) = 40 msec
    - 5 mm (1 large square) = 200 msec
  - the vertical axis represents voltage (at usual standard gain setting 10 mm/mV)
    - 1 mm (1 small square) = 0.1 mV
    - 10 mm (2 large squares) = 1 mV
Approach to ECGs

Indications for brief (12-lead ECG) or prolonged (24 hrs or more) monitoring
- detect myocardial injury, ischemia, and the presence of prior infarction
- conditions associated with palpitations or risk of serious arrhythmias (e.g. WPW, long QT, HCM, heart block, and bradycardia)
- recording of cardiac rhythm during symptoms or antiarrhythmic drug monitoring
- conduction abnormalities (e.g. LBBB/RBBB)
- electrolytes abnormalities (e.g. hyperkalemia/hypokalemia)
- assessment of cardiac structure and function. (e.g. RVH/LVH and cardiomyopathy)
- non-sustained arrhythmias that can lead to prophylactic intervention

Approach to ECGs

Introduction
Below, we are presenting both the Classical Approach and the newer PQRSTU Approach to provide students with different ways to view the ECG. Despite methodological differences, the rigor and final result is the same.

Classical Approach to ECGs

RATE
- normal = 60-100 bpm (atrial rate: 150-250 bpm = paroxysmal tachycardia, 250-350 bpm = atrial flutter, >350 bpm = AFib, in AF atrial "rate" not discernible)
- regular rhythm (defined by equal R-R or P-P intervals between beats)
  - to calculate the rate, divide 300 by number of large squares between 2 QRS complexes (there are 300 large squares in 1 min: 300 x 200 msec = 60 sec)
  - or use the square counting method by counting the number of big boxes between the R waves using the following numbers: 300-150-100-75-60-50
- irregular rhythm
  - rate = 6 x number of R-R intervals in 10 s (the “rhythm strips” are 10 sec recordings)
  - atrial escape rhythm in case of sinus node failure = 60-80 bpm; junctional escape rhythm = 40-60 bpm; ventricular escape rhythm = 20-40 bpm

RHYTHM
- regular: R-R interval is the same across the tracing
- irregular: R-R interval varies across the tracing
- regularly irregular: repeating pattern of varying R-R intervals e.g. Atrial flutter with variable block
- irregularly irregular: R-R intervals vary erratically e.g. AFib, VFib
- normal sinus rhythm (NSR)
  - P wave precedes each QRS; QRS follows each P wave
  - P wave axis is normal (positive in 2 out of the 3 following leads I, II, aVF)
  - rate between 60-100 bpm

AXIS
- mean axis indicates the direction of the mean vector
- can be determined for any waveform (E, QRS, T)
- the standard ECG reported QRS axis usually refers to the mean axis of the frontal plane – it indicates the mean direction of ventricular depolarization forces
- QRS axis in the frontal plane
  - normal axis: -30° to 90° (i.e. positive QRS in leads I and II)
  - left axis deviation (LAD): axis <-30°
  - right axis deviation (RAD): axis >90°
- QRS axis in the horizontal plane is not routinely calculated
  - transition from negative to positive is usually in lead V3

Figure 7. Axial reference system
Each lead contains a (+) area displayed by the bold arrows. Impulses traveling toward the positive region of the lead results in an upward deflection in that lead. Normal QRS axis is between -30° and +90°

</tbody>
</table>

ISCHEMIA/INFARCTION
- look for the anatomic distribution of the following ECG abnormalities (see Table 3)
  - ischemia
    - ST segment depression
    - T wave inversion (most commonly in V1-V6)
  - injury/infarct
    - transmural (involving the epicardium)
    - ST elevation in the leads facing the area injured/infarcted
    - subendocardial
    - marked ST depression in the leads facing the affected area
  - may be accompanied by enzyme changes and other signs of MI

Figure 10. Typical ECG changes with infarction
- ST elevation
  - new ST elevation in two contiguous leads of >0.1 mV in all leads other than leads V2-V3
  - for leads V2-V3: ≥0.2 mV in men ≥40 yr, ≥0.25 mV in men <40 yr, or ≥0.15 mV in women
Approach to ECGs

• “typical” sequential changes of evolving MI
  1. Hyperacute T waves (tall, symmetric T waves) in the leads facing the infarcted area, with or without ST elevation
  2. ST elevation (injury pattern) in the leads facing the infarcted area
    • usually in the first hours post infarct
    • in acute posterior MI, there is ST depression in V1-V3 (reciprocal to ST elevation in the posterior leads that are not recorded in the standard 12-lead ECG) hence get a 15-lead ECG
  3. Significant Q waves: >40 msec or >1/3 of the total QRS amplitude and present in at least 2 consecutive leads in the same territory (hours to days post-infarct)
    • Q waves of infarction may appear in the very early stages, with or without ST changes
    • non-Q wave infarction: there may be only ST or T changes despite clinical evidence of infarction
  4. Inverted T waves (one day to weeks after infarction)

• Completed infarction
  • Abnormal Q waves (Q waves may be present in lead III in normal individuals due to initial septal depolarization)
  • Duration >40 msec (>30 msec in aVF for inferior infarction)
  • Q wave is >1/3 of the total QRS amplitude
  • Present in at least 2 consecutive leads in the same territory
  • Abnormal R waves (R/S ratio >1, duration >40 msec) in V1 and occasionally in V2 are found in posterior infarction (usually in association with signs of inferior and/or lateral infarction)

Table 3. Areas of Infarction/Ischemia (right dominant anatomy)

</table>

MISCELLANEOUS ECG CHANGES

Electrolyte Disturbances
• Hyperkalemia
  • Mild to moderate (K+ 5-7 mmol/L): tall, peaked T waves
  • Severe (K+ >7 mmol/L): progressive changes whereby P waves flatten and disappear, QRS widens and may show abnormal morphology, axis shifts left or right, ST shift with tall T waves, eventually becomes a “sine wave” pattern
• Hypokalemia
  • ST segment depression, prolonged QT interval (with risk for torsades de pointes ventricular tachycardia if extreme), low T waves, prominent U waves (U>T)
  • Enhances the toxic effects of digoxin
• Hypercalcemia
  • Shortened QT interval (more extracellular Ca2+ means shorter plateau in cardiac action potential)
• Hypocalcemia
  • Prolonged QT interval (less extracellular Ca2+ means longer plateau in cardiac action potential)

Figure 11. Hyperkalemia

Figure 12. Hypokalemia

Hypothermia
• Sinus bradycardia
• When severe, prolonged QRS and QT intervals
• AFib with slow ventricular response and other atrial/ventricular dysrhythmias
• Osborne J waves: “hump-like” waves at the junction of the J point and the ST segment

Pericarditis
• Early: diffuse ST segment elevation ± PR segment depression, upright T waves
• Later: isoelectric ST segment, flat or inverted T waves
• ± Tachycardia
Drug Effects
- digitalis – rare in 2018; <1/1000 cardiac patients overall
  - therapeutic levels may be associated with “digitalis effect”
    - ST downsloping or “scooping”
    - T wave depression or inversion
    - QT shortening ± U waves
    - slowing of ventricular rate in AFib
  - toxic levels associated with:
    - arrhythmias: paroxysmal atrial tachycardia (PAT) with conduction block, severe bradycardia in AFib, accelerated junctional rhythms, PVCs, ventricular tachycardia (see Arrhythmias, C16)
    - “regularization” of ventricular rate in AFib due to a junctional rhythm and AV dissociation
- amiodarone, quinidine, phenothiazines, tricyclic antidepressants, antipsychotics, some antihistamines, and some antibiotics (prolonged QT interval, U waves)

Figure 14. Atrial fibrillation, ST change due to digitalis (“digitalis effect”)

Pulmonary Disorders
- cor pulmonale (often secondary to COPD)
  - low voltage, right axis deviation (RAD), poor R wave progression in precordial leads
  - RAE and RVH with strain
  - multifocal atrial tachycardia (MAT)
- massive pulmonary embolism (PE)
  - sinus tachycardia and AFib/atrial flutter are the most common arrhythmias
  - RAD, RVH with strain
  - most specific sign is S1Q3T3 (S in I, Q and inverted T wave in III) but rather uncommon

Alternative PQRSTU Approach to ECGs

Note: the PQRSTU Approach is organized a different way based on the anatomy of the ECG
P WAVE
• the P wave represents atrial contraction; best seen in leads: II and V1
  • lead II: the P wave should be rounded, <120 msec and <2.5 mm in height
  • lead V1: the P wave is biphasic with a positive phase slightly greater than the negative phase
• atrial flutter: sawtooth P wave with continuous atrial activity at 300/min indicates the interval (Hint: flip the ECG upside-down to see it better if unclear)
• atrial fibrillation: absent P wave, may have fibrillatory wave, irregular rhythm
  • right atrial enlargement: tall P wave (>2.5 mm) in II or V1 (P pulmonale)
  • left atrial enlargement: biphasic P wave with negative deflection >1 mm deep or >1 mm wide in V1, wide (>100 msec) notched P wave in II may be present (P mitrale)

P-R INTERVAL
• the P-R interval indicates the interval between sinus node activation and the start of ventricular depolarization
  • includes the impulse traveling through the atrium, the AV node, and the bundle of the magnitude of the conduction velocity is referred to as “dromotropy” (faster = positive, slower = negative dromotropy)
  • positive dromotropy associated with increased conduction velocity (e.g. sympathetic stimulation), while negative dromotropy with decreased velocity (e.g. vagal stimulation)
• P-R interval should be 120-200 msec
  • short P-R interval (>200 msec)
  • heart block
    • first degree: fixed, prolonged P-R interval (though every P wave has a QRS following)
    • second and third degree AV block: some P waves are NOT followed by a QRS
      • second degree Mobitz I (Wenckebach): gradual prolongation of the P-R interval precedes a dropped P wave
      • second degree Mobitz II (Hay): fixed P-R interval with ratio of beat to dropped beat (e.g. for every 3 beats, there is one dropped beat [3:1])
    • third degree/complete: constant P-F and R-R intervals but variable P-R intervals
      • sinus bradycardia (normal to have long P-R if heart rate slow)
      • hypokalemia
      • “trifascicular” block - 1st degree AV block with LAHF and complete RBBB
  • short P-R interval (<120 msec)
    • pre-excitation syndrome (delta wave: upswoooping of P-R segment into QRS complex) due to accessory pathways
    • low atrial rhythm, P waves inverted in II, III, aVF

QRS COMPLEX
• represents ventricular contraction
• rate: check if R-P interval matches the P-P interval
• amplitude: check for hypertrophy (see Table 2)
• narrow QRS (<120 msec) means that the His-Purkinje system is being used
  • wide QRS (>120 msec) means that the His-Purkinje system is being bypassed or is diseased
    • BBB, VT, ventricular cardiomyopathy, WPW, ectopic ventricular beat, hyperkalemia, or drugs (e.g. TCAs, antiarrhythmics)
• Q wave: the first downward deflection of the QRS complex
  • significant Q wave (>40 msec or >1/3 of total QRS amplitude) indicates myocardial necrosis (new or old)
  • R and S wave abnormalities typically show pathology in terms of BBB or intraventricular abnormalities

ST SEGMENT
• located between QRS complex and the beginning of T wave
• corresponds to the completion of ventricular depolarization
• normally at the same level as baseline (T-P segment)
• ST elevation: please see the infarction section above
• ST depression: ischemia
  • ischemia which causes ST depression can result in myocardial damage (NSTEMI)
    • lateral ST depression (leads I, aVL, V5, V6) may actually indicate a STEMI in the right heart
  • ST depression may be nonspecific, or associated with remote myocardial infarction or ischemia

T WAVE
• repolarization phase of ventricles (repolarization of the atria is obscured by the QRS complex)
• typically positive (except in aVR and V1) on ECG but normal isolated negative T waves may be present (especially in V1 and V2)
• pathology when T wave variation occur in consecutive leads
  • inversion: BBB, ischemia, hypertrophy, drugs (e.g. digitalis), pulmonary embolism (lead III as part of S1Q3T3 sign)
  • elevation: infarction (STEMI, Prinzmetal, hyperacute), hyperkalemia (wider, peaked)
  • flattened: hypokalemia, pericarditis, drugs (e.g. digitalis), pericardial effusion
  • T waves may be flat as a nonspecific finding without clinical significance (common)
• variations: T wave alternans; beat-to-beat variations due to PVC overlap (R on T phenomenon which may precipitate VT or VFib)
• appropriate T wave discordance: in BBB, T wave deflection should be opposite to that of the terminal QRS deflection (i.e. T wave negative if ends with R or R'; positive if ends with S)
• inappropriate T wave concordance suggests ischemia or infarction
**Q-T INTERVAL**
- duration of ventricular depolarization plus repolarization; often difficult to interpret
- corrected QT (QTc) corrects for the repolarization duration (since QT interval normally shortens with increased heart rate)
  - $\text{QTc} = \text{QT} \div \sqrt{RR}$ (Bazett's formula)
- normal QTc is 360-450 msec for males and 360-460 msec for females
- increased (>450 msec for males and >460 msec for females): risk of Torsades de Pointes (lethal tachyarrhythmia; rare if <520 msec)
  - genetic Long QT Syndrome (often a channelopathy)
  - drugs: antiarrhythmics (class I and III), antipsychotics (haloperidol, ziprasidone), antidepressants (citalopram), antibiotics (erythromycin, azithromycin)
  - electrolytes: low Ca++, low K+, low Mg++
  - others: hypothyroidism, hypothermia, cardiomyopathy
- decreased (<360 msec): risk of VFib (very rare)
  - electrolytes: high Ca++
  - drugs: digoxin
  - others: hyperthyroidism

**U WAVE**
- origin unclear but may be repolarization of Purkinje fibres or delayed/prolonged repolarization of the myocardium
- more visible at slower heart rates
- deflection follows T wave with <25% of the amplitude
- variations from norm could indicate pathologic conditions
  - prominent (>25% of T wave); electrolyte (low K+), drugs (digoxin, antiarrhythmics)
  - inverted (from T wave): ischemia, volume overload

**Cardiac Biomarkers**
- provide diagnostic and prognostic information in acute coronary syndromes and in heart failure

**Table 4. Cardiac Enzymes**

<table>
<thead>
<tr>
<th>Enzyme</th>

</tr>
<tr>
<td>CK-MB</td>
<td>1 d</td>
<td>3 d</td>
<td>MI, myocarditis, pericarditis, muscular dystrophy, cardiac defibrillation, chronic renal insufficiency</td>
</tr>
</tbody>
</table>

- check troponin I at presentation and 8 h later ± creatine kinase-MB (CK-MB; depends on local laboratory protocol)
- new CK-MB elevation can be used to diagnose re-infarction
- other biomarkers of cardiac disease
  - AST and LDH also increased in MI (low specificity)
  - BNP and NT-proBNP: secreted by ventricles in response to increased end-diastolic pressure and volume
  - DDx of elevated BNP: CHF, AFib, PE, COPD exacerbation, pulmonary HTN

**Ambulatory ECG**
- description
  - extended ambulatory ECG monitoring
  - provides a view of only two or three leads of electrocardiographic data over an extended period of time
  - permits evaluation of changing dynamic cardiac electrical phenomena that are often transient
  - continuous ambulatory monitor: a small, lightweight, battery operated recorder (box or patch) that records two or three channels of electrocardiographic data
    - patient activated event markers
    - minimum of 24-72 h, up to 14 d
  - implantable device: subcutaneous monitoring device for the detection of cardiac arrhythmias
    - typically implanted in the left pectoral region and stores events when the device is activated automatically according to programmed criteria or manually with magnet application
    - generally used for months to years of continuous monitoring for infrequent events
- indications
  - evaluation of cardiac rhythm abnormalities, especially as they correlate with symptoms
  - has also been used for assessing pacemaker and implantable cardioverter-defibrillator function, evidence of myocardial ischemia, late potentials, and heart rate variability

**Use of B-Type Natriuretic Peptide in the Evaluation and Management of Acute Dyspnea (BASEL)**
NEJM 2004;350;647-54
Study: Prospective, RCT.
Population: 426 patients (mean age 71 yr, 58% male) with acute dyspnea; patients with severe renal disease or cardiogenic shock were excluded.
Intervention: Assessment including measurement of B-type natriuretic peptide or standard assessment.
Outcome: Time to discharge and total cost of treatment.
Results: Median time to discharge was significantly shorter in the intervention group when compared with the control group (8.0 vs. 11.0 d, p=0.001). Total cost was also significantly lower in the intervention group ($4610 vs. $7264, p=0.006). In addition, the measurement of B-type natriuretic peptide significantly reduced the need for admission to hospital and intensive care. The 30-d mortality rates were similar (10% vs. 12%, p=0.46).
Conclusions: In patients with acute dyspnea, measurement of B-type natriuretic peptide improves clinical outcomes (need for hospitalization or intensive care) and reduces time to discharge and total cost of treatment.
Echocardiography

**Transthoracic Echocardiography (TTE)**
- **description**
  - ultrasound beams are directed across the chest wall to obtain images of the heart
- **indications**
  - evaluation of chamber size, LVEF, wall motion abnormalities, myocardial ischemia and complications of MI
  - evaluation of wall thickness, valve morphology, proximal great vessel morphology, pericardial effusion
  - evaluation of unexplained hypotension, murmurs, syncope, and congenital heart disease or other cardiac symptoms and unexplained signs on physical exam (i.e. leg edema)

**Transoesophageal Echocardiography (TEE)**
- **description**
  - invasive procedure used to complement TTE
  - ultrasound probe inserted into the esophagus to allow for better resolution of the heart and structures
  - better visualization of posterior structures, including left atrium, mitral, and aortic valves, inter-atrial septum
- **indications**
  - should be performed as the initial test in certain life-threatening situations (e.g. aortic dissection)
  - when other tests contraindicated (e.g. CT angiography in patient with renal failure)
  - most importantly, TTE is used to evaluate valvular morphology and function (particularly the aortic and mitral valves)
  - intracardiac thrombi, tumours, valvular vegetations (infective endocarditis), aortic dissection, aortic atheromas, prosthetic valve function, shunt, technically inadequate transthoracic study
  - evaluation for left atrial thrombus/left atrial appendage thrombus in a patient with atrial fibrillation/atrial flutter to facilitate clinical decision making regarding electrical cardioversion or ablation
- **risks**
  - serious complications are extremely rare (<1 in 5000)
  - esophageal perforation
  - gastrointestinal bleeding
  - pharyngeal hematoma

**Stress Echocardiography (SE)**
- **description**
  - echocardiography using exercise (treadmill or bicycle) or pharmacologic agents (dobutamine or adenosine) as physiologic stressor
- **indications**
  - useful alternative to other stress imaging modalities
  - when ECG cannot be interpreted appropriately
  - intermediate pre-test probability with normal/equivocal exercise ECG
  - post-ACS when used to decide on potential efficacy of revascularization
  - to evaluate the clinical significance of valvular heart disease
  - evaluation of myocardial viability, dyspnea of possible cardiac origin, mitral valve disease, aortic stenosis, mitral regurgitation, pulmonary hypertension, and patients with hypertrophic cardiomyopathy (for LVOT obstruction)
  - dobutamine
    - pharmacologic stress for patients physically unable to exercise; same indications as exercise stress echo
    - low dose dobutamine stress echo can be used to assess myocardial viability and for assessing aortic stenosis with LV systolic dysfunction
- **contraindications**
  - contraindications to exercise testing (see below)
  - contraindications to dobutamine stress echocardiography: tachyarrhythmias and systemic hypertension
  - AAA has been considered as a relative contraindication to exercise testing or dobutamine stress echocardiography

**Contrast Echocardiography with Agitated Saline Contrast**
- **description**
  - improves visualization and provides real-time assessment of intracardiac blood flow
  - conventional agent is agitated saline (contains microbubbles of air)
  - visualization of right heart and intracardiac shunts, most commonly patent foramen ovale (PFO) and intrapulmonary shunt

**Contrast Echocardiography with Transpulmonary Contrast Agents**
- **description**
  - newer contrast agents are capable of crossing the pulmonary bed and achieving left heart opacification following intravenous injection; these contrast agents improve visualization of endocardial borders and enhance evaluation of LV ejection fraction and wall motion abnormalities (in patients with technically inadequate echocardiograms) and intracardiac mass (e.g. LV thrombus)
- **risks**
  - risk of non-fatal MI and death are rare
  - ultrasound contrast agents may cause back pain, headache, urticaria, and anaphylaxis
  - should not be done in patients with significant intra-cardiac shunts
Stress Testing

**EXERCISE TESTING**
- **description**
  - cardiovascular stress test that uses treadmill or bicycle exercise with electrocardiographic and blood pressure monitoring
- **indications**
  - patients with intermediate (10-90%) pretest probability of CAD based on age, gender, and symptoms
  - ST depression <1 mm at rest, no left bundle branch block, no digoxin or estrogen use
  - exercise test results stratify patients into 3 risk groups
    1. low risk patients can be treated medically without invasive testing
    2. intermediate risk patients may need additional testing in the form of exercise imaging studies or cardiac catheterization
    3. high risk patients should be referred for cardiac catheterization
- **contraindications**
  - acute myocardial infarction (within 2 d) or unstable angina pectoris
  - uncontrolled arrhythmias causing symptoms of hemodynamic compromise
  - symptomatic severe valvular stenosis
  - uncontrolled symptomatic heart failure
  - active endocarditis or acute myocarditis or pericarditis
  - acute aortic dissection
  - acute pulmonary or systemic embolism
  - acute non-cardiac disorders that may affect exercise performance or may be aggravated by exercise
  - termination of exercise testing
    - patient's desire to stop
    - drop in systolic blood pressure of >10 mmHg from baseline despite an increase in workload, when accompanied by other evidence of ischemia
    - moderate to severe angina
    - ST elevation (>1 mm) in leads without diagnostic Q-waves (other than V1 or aVR)
    - increasing nervous system symptoms (e.g. ataxia, dizziness, or near syncope)
    - signs of poor perfusion (cyanosis or pallor)
    - technical difficulties in monitoring ECG or systolic blood pressure
    - sustained ventricular tachycardia
- **risks**
  - death, myocardial infarction, arrhythmia, hemodynamic instability, and orthopedic injury (<1-5/10,000 supervised tests)

**NUCLEAR CARDIOLOGY**
- **description**
  - myocardial perfusion imaging (MPI) with ECG-gated single photon emission computed tomography (SPECT), using radiolabelled tracer
  - evaluates myocardial viability, detects ischemia, and assesses perfusion and IV function simultaneously
  - predicts the likelihood of further cardiac event rates independent of the patient's history, examination, resting ECG, and stress ECG
  - often denoted as MIBI scan with reference to radiolabelled tracer (sestamibi)
  - stress with either treadmill or IV vasodilator stress (dipyridamole, adenosine, regadenoson)
  - images of the heart obtained during stress and at rest 3-4 h later
  - tracers
    - Thallium-201 ($^{201}$TI, a K+ analogue)
    - Technetium-99 ($^{99}$Tc)-labeled tracer (sestamibi/Cardiolite® or hexamibi/Myoview®)
- **indications**
  - to diagnose CAD in possible ACS patients with non-diagnostic ECG and negative serum biomarker
  - exercise MPI
    - when ECG cannot be interpreted appropriately due to LBBB or abnormal baseline ECG
    - intermediate pre-test probability with normal/equivocal exercise ECG
    - in patients with previous imaging whose symptoms have changed
    - to diagnose ischemia
  - dipyridamole/adenosine MPI
    - exercise testing is always preferred
    - pharmacological stress imaging test for patients who cannot exercise or do not want to hold cardiac meds (BB/CCBs)
    - same indication as exercise MPI
- **contraindications**
  - contraindications to exercise testing
    - vasodilators (i.e. adenosine, regadenoson, and dipyridamole) are contraindicated in patients with hypotension, sick sinus syndrome, high-degree AV block (in the absence of backup pacemaker capability), and reactive airways disease
  - pregnancy
- **risks**
  - radiation exposure

**STRESS ECHOCARDIOGRAPHY**
- see Echocardiography, C12
Cardiac Catheterization and Angiography

Right Heart Catheterization (Swan-Ganz Catheter)

- description
  - also known as pulmonary artery catheterization
  - obtain direct measurements of central venous, right-sided intracardiac, pulmonary artery, and pulmonary artery occlusion pressures
  - can estimate cardiac output, systemic and pulmonary vascular resistance as well as mixed venous oxyhemoglobin saturation, oxygen delivery, and oxygen uptake
  - right atrial, right ventricular, and pulmonary artery pressures are recorded
  - can also be used to measure the Cardiac Index (CI), a measure of cardiac function
    - CI = CO/body surface area
    - 2.6-4.2 L/min/m² is considered normal while <1.8 L/min/m² usually means cardiogenic shock
  - pulmonary capillary wedge pressure (PCWP)
    - obtained by advancing the catheter to wedge in the distal pulmonary artery
    - records pressure measured from the pulmonary venous system
    - in the absence of pulmonary venous disease reflects left atrial pressure

- indications
  - unexplained or unknown volume status in shock
  - severe cardiogenic shock (e.g. acute valvular disease, suspected pericardial tamponade)
  - suspected or known pulmonary artery hypertension
  - severe underlying cardiopulmonary disease (e.g. congenital heart disease, left-to-right shunt, severe valvular disease, pulmonary hypertension) and undergoing corrective or other surgery

- contraindications
  - infection at the insertion site
  - presence of a right ventricular assist device
  - insertion during cardiopulmonary bypass

- risks
  - complications for diagnostic catheterization <1%
  - inadequate diagnostic procedures occur in <1% of cases
  - complications of insertion: atrial and/or ventricular arrhythmias (~3% of patients)
  - catheter misplacement or knotting (uncommon)
  - perforation of a cardiac chamber and rupture of a cardiac valve or the pulmonary artery (rare)
  - complications of catheterization: pulmonary artery rupture, pulmonary infarction, thromboembolic events, infection, and data misinterpretation
  - within 24 h of catheterization: death, MI, or stroke (0.2% to 0.3% of patients)

Figure 17. Swan-Ganz catheter placement

© Kateryna Procnier 2015
Left Heart Catheterization

- **description**
  - accomplished by introducing a catheter into the brachial or femoral artery and advancing it through the aorta, across the aortic valve, and into the left ventricle
  - evaluates mitral and aortic valvular defects and myocardial disease
  - systolic and end-diastolic pressure tracings recorded
  - LV size, wall motion and ejection fraction can be assessed by injecting contrast into the LV (left ventriculography) via femoral/radial artery catheterization
  - cardiac output (measured by the Fick oxygen method or the indicator dilution method)

- **indications**
  - identification of the extent and severity of CAD and evaluation of left ventricular function
  - assessment of the severity of valvular or myocardial disorders (e.g. aortic stenosis or insufficiency, mitral stenosis or insufficiency, and various cardiomyopathies) to determine the need for surgical correction
  - collection of data to confirm and complement noninvasive studies
  - investigating CAD in patients with confusing clinical features or chest pain of uncertain origin

- **contraindications**
  - severe uncontrolled hypertension
  - ventricular arrhythmias
  - acute stroke
  - severe anemia
  - active gastrointestinal bleeding
  - allergy to radiographic contrast
  - acute renal failure
  - uncontrolled congestive failure (patient cannot lie flat)
  - unexplained febrile illness or untreated active infection
  - electrolyte abnormalities (e.g. hyperkalemia)
  - severe coagulopathy

- **risks**
  - major complications for diagnostic catheterization (death, MI, stroke) <3 in 1000
  - minor complications e.g. vascular assess issue, kidney dysfunction <1 in 100
  - inadequate diagnostic procedures occur in <1% of cases

Coronary Angiography

- **description**
  - radiographic visualization of the coronary vessels after injection of radiopaque contrast media
  - coronary vasculature accessed via the coronary ostia

- **indications**
  - to define the coronary anatomy and the degree of luminal obstruction of the coronary arteries
  - to determine the presence and extent of obstructive CAD
  - to assess the feasibility and appropriateness of various forms of therapy, such as revascularization by percutaneous or surgical interventions
  - can be used when the diagnosis of CAD is uncertain and cannot be excluded by noninvasive techniques

- **contraindications**
  - severe renal failure due to contrast agent toxicity (must check patient’s renal status due to contrast agent toxicity)

- **risks**
  - major complications for diagnostic catheterization (death, MI, stroke) <3 in 1000
  - minor complications e.g. vascular assess issue, kidney damage <1/100

ACC/AHA 2011 Recommended Indications for Coronary Angiography

- Disabling (CCS classes III and IV) chronic stable angina despite medical therapy
- High-risk criteria on clinical assessment or non-invasive testing
- Serious ventricular arrhythmia or CHF
- Uncertain diagnosis or prognosis after non-invasive testing
- Inability to undergo non-invasive testing

Coronary Angiography

Gold standard for localizing and quantifying CAD

Hemodynamically significant stenosis is defined as 70% or more narrowing of the luminal diameter

---

**Figure 18. Coronary angiogram schematic**

AM = acute marginal; LAD = left anterior descending; OM = obtuse marginal; RCA = right coronary artery
Diagnostic Catheterization
- provocative pharmacological agents can be used to unmask pathology
  - fluid loading may unmask latent pericardial constriction
  - afterload reduction or inotropic stimulation may be used to increase the outflow tract gradient in HCM
  - coronary vasoreactive agents (e.g. methylergonovine, acetylcholine)
  - a variety of pulmonary vasoreactive agents in primary pulmonary HTN (e.g. oxygen, calcium channel blockers, adenosine, nitric oxide, prostacyclin)

Contrast-Enhanced CT Coronary Angiography
- **description**: fast ECG-synchronized multi-slice CT image acquisition in the heart to enable non-invasive imaging of the coronary arterial tree
- **indications**: often used to assess coronary artery and previous graft stenosis/viability that could not be seen during coronary angiography
  - sensitivity = 85%, specificity = 90% for the diagnosis of obstructive coronary disease with >50% stenosis
- **contraindications**: allergy to contrast dye; severe renal dysfunction
- **risks**: radiation exposure

Magnetic Resonance Imaging
- **description**: offers high spatial resolution, eliminates the need for iodinated contrast, and does not involve exposure to ionizing radiation
- **indications**: valuable in assessment of congenital cardiac anomalies, abnormalities of the aorta, assessment of viable myocardium, and assessment of cardiomyopathies
- **contraindications**: metallic foreign bodies/implants, kidney dysfunction due to gadolinium contrast medium
- **risks**: hazards posed by certain metallic devices inside patients

Arrhythmias
Mechanisms of Arrhythmias

Alterations in Impulse Formation

A. Normal Automaticity
- impulses from the SA node, caused by spontaneous depolarization, result in the basic cardiac pacemaker function. "Downstream" cells in the AV node and Purkinje fibres also depolarize spontaneously, but at a slower rate; they serve as the "backup" pacemaking cells if the upstream rate is slower than the more distal spontaneous rate.
- normal automaticity is influenced by:
  - neurohormonal tone (sympathetic tone increases and parasympathetic tone decreases spontaneous firing rate and thus heart rate)
  - myocardial ischemia/infarction or other cardiac pathology (e.g. heart failure) may alter heart rate via these mechanisms
  - abnormal metabolic conditions (e.g. hypoxia, acidosis, hypothermia)
  - electrolyte abnormalities, especially hyperkalemia which slows heart rate
  - drugs (e.g. digitalis, beta blockers, calcium channel blockers)

B. Abnormal Automaticity due to Triggered Activity (due to Afterdepolarizations)
1. Early Afterdepolarizations
- during the terminal plateau or repolarization phases of action potential
  - consequence of the membrane potential transiently becoming more positive during repolarization (depolarization interrupting repolarization)
  - these are called EADs and DADs (early and delayed afterdepolarization, respectively)
  - may result in self-maintaining oscillations of depolarization, giving rise to action potentials thereby generating a tachyarrhythmia (e.g. new baseline voltage is greater than threshold, which automatically triggers a new action potential after the refractory period ends)
- EADs are the basis for the arrhythmias associated with QT prolongation, either congenital or acquired; termed "Torsades de Pointes"
2. Delayed Afterdepolarizations
- occur after the action potential has fully repolarized, but before the next usual action potential
- commonly occurs in situations of high intracellular calcium (e.g. digitalis intoxication, ischemia) or during enhanced catecholamine stimulation (e.g. “twitchy” pacemaker cells)

Alterations in Impulse Conduction

A. Re-Entry Circuits
- the presence of self-sustaining re-entry circuit causes rapid repeated depolarizations in a region of myocardium (see Figure 26, C20, for an example in the context of AV nodal re-entrant tachycardia)
- the conditions necessary for reentry include block of an impulse into a region of the heart that is refractory (non-excitable tissue or because of local functional block, where the impulse encounters tissue still in its refractory period), followed by “reentry” of the impulse around a region of block to the site of origin, forming a complete reentry circuit
  - e.g. myocardium that is infarcted/ischemic will consist of non-excitable and partially excitable zones which will promote the formation of re-entry circuits

B. Conduction Block
- ischemia, fibrosis, trauma, and drugs can cause transient or permanent, unidirectional or bidirectional block
- most common cause of block is due to refractory myocardium (cardiomyocytes are in refractory period or zone of myocardium unexcitable due to fibrosis)
- cells in the conduction system distal to the block can assume pacemaking control if the block occurs along the specialized conduction system
- conduction block can lead to bradycardia

C. Bypass Tracts
- normally, the only electrical connection between atria (A) and ventricles (V) is the AV node and penetrating Bundle of His
- an accessory bypass tract is a direct connection between atrium and ventricle, histologically similar to atrial tissue, through the valve ring which is impervious to electrical impulses
  - see Pre-Excitation Syndromes, C21

---

Bradyarrhythmias

1. SA NODAL DYSFUNCTION

A. Sinus Bradycardia

P axis normal (P waves positive in I and aVF) Rate <60 bpm; marked sinus bradycardia (<50 bpm) May be seen in normal adults, particularly athletes, and in elderly individuals Increase vagal tone or vagal stimulation; drugs (e.g. β-blockers, calcium channel blockers); ischemia/infarction Atriptine; pacing for sick sinus syndrome

Figure 20. Sinus bradycardia

2. AV CONDUCTION BLOCKS

A. First Degree AV Block

Prolonged PR interval (>220 msec) Frequently found among otherwise healthy adults No treatment required

Figure 21. First degree AV block

B. Second Degree AV Block: Type I (Mobitz I)

A gradual prolongation of the PR interval precedes the failure of conduction of a P wave (Wenckebach phenomenon) AV block is usually in AV node (proximal triggers usually reversible); increased vagal tone (e.g. following surgery), RCA-mediated ischemia

Figure 22. Second degree AV block with Wenckebach phenomenon (Mobitz I) (4:3 conduction) (lead V1)

B. Second Degree AV Block: Type II (Mobitz II)

The PR interval is constant; there is an abrupt failure of conduction of a P wave Often associated with distal conduction system disease (bundle branch block) AV block is usually distal to the AV node (i.e. bundle of His); increased risk of high grade or 3rd degree AV block

Figure 23. Second degree AV block (Mobitz II) (3:2 conduction) (lead V1)

B. Third Degree AV Block

Complete failure of conduction of the supraventricular impulses to the ventricles; ventricular depolarization initiated by an escape pacemaker distal to the block Wide or narrow QRS, P-P and R-R intervals are constant, variable PR intervals; no relationship between P waves and QRS complexes (P waves “marching through”) Management (see Electrical Pacing, C24)

Figure 24. Third degree AV block (complete heart block) (lead II)

Supraventricular Tachyarrhythmias

Presentation for SVT (and Pre-Excitation Syndromes)

- presentation can include: palpitations, dizziness, dyspnea, chest discomfort, presyncope/syncope
- may precipitate CHF, hypotension, or ischemia in patients with underlying cardiovascular disease
- untreated tachycardias of long duration (days) can cause tachycardia induced cardiomyopathy (rare, potentially reversible with treatment of SVTs)
- arrhythmias involving the AV node (AVNRT and AVRT) may terminate spontaneously, after vagal stimulation, or adenosine treatment

Supraventricular Tachyarrhythmias

- tachyarrhythmias that originate in the atria or AV junction
- this term is used when a more specific diagnosis of mechanism and site of origin cannot be made
- characterized by narrow QRS unless there is pre-existing bundle branch block or aberrant ventricular conduction (abnormal conduction due to a change in cycle length)

1. Sinus Tachycardia

- sinus rhythm with rate >100 bpm
- occurs in normal subjects with increased sympathetic tone (e.g. exercise, anxiety, pain, pregnancy), alcohol use, caffeinated beverages, drugs (e.g. β-adrenergic agonists, anticholinergic drugs)
- systemic etiology: fever, hypotension, hypervolemia, anemia, thyrotoxicosis, CHF, MI, shock, pulmonary embolism
- treatment: treat underlying disease; consider β-blocker if symptomatic, calcium channel blocker if β-blockers contraindicated; ivabradine may be considered as an alternative agent for inappropriate sinus tachycardia
2. Premature Beats
- premature atrial contraction
  - ectopic supraventricular beat originating in the atria
  - P wave morphology of the PAC usually differs from that of a normal sinus beat
- junctional premature beat
  - ectopic supraventricular beat that originates in the vicinity of the AV node
  - P wave is usually not seen or an inverted P wave is seen and may be before or closely follow the QRS complex (referred to as a retrograde, or “traveling backward” P wave)
- treatment usually not required

3. Atrial Flutter
- rapid, regular atrial depolarization from a macro re-entry circuit within the atrium (most commonly right atrium)
- atrial rate 250-350 bpm, usually 300 bpm
- AV block usually occurs; it may be fixed (e.g. 2:1, 3:1, 4:1, etc.) or variable
- etiology: hypertension, cardiomyopathy, in association with atrial fibrillation; less often, CAD, thyrotoxicosis, mitral valve disease, cardiac surgery, COPD, PE, pericarditis
- ECG: sawtooth flutter waves (most common type of flutter, called “isthmus dependent, typical flutter”) in inferior leads (II, III, aVF); narrow QRS (unless aberrancy); commonly seen as 2:1 block with HR of 150
- in atrial flutter with 2:1 block, carotid sinus massage (first check for bruits), Valsalva maneuver, or adenosine may decrease AV conduction and allow flutter waves to be more easily seen
- treatment of acute atrial flutter
  - if unstable (e.g. hypotension, CHF, angina): electrical cardioversion
  - if stable:
    1. rate control: β-blocker, diltiazem, verapamil, or digoxin
    2. chemical cardioversion: sotalol, amiodarone, type I antiarrhythmics, or electrical cardioversion
- anticoagulation guidelines same as for patients with AFib
- treatment of long-term AFib includes antiarrhythmics and radiofrequency (RF) ablation (success rate dependent on site of origin of atrial flutter)

4. Multifocal Atrial Tachycardia (MAT)
- irregular rhythm caused by presence of 3 or more atrial foci (may mimic AFib)
- atrial rate 100-200 bpm
- 3 or more distinct P wave morphologies and PR intervals vary, some P waves may not be conducted
- occurs more commonly in patients with COPD and hypoxemia; less commonly in patients with hypokalemia, hypomagnesemia, sepsis, theophylline, or digitalis toxicity
- treatment: treat the underlying cause; calcium channel blockers may be used (e.g. diltiazem, verapamil), β-blockers may be contraindicated because of severe pulmonary disease
- no role for electrical cardioversion, antiarrhythmics, or ablation

5. Atrial Fibrillation
- see CCS Atrial Fibrillation Guidelines 2016 for details (free mobile app – iCCS available on iOS and Android)
- most commonly sustained arrhythmia
- incidence increases with age (10% of population >80 yr)
- symptoms: palpitations, fatigue, dyspnea, syncope, may precipitate or worsen heart failure
- classification
  - lone: generally occurs in persons <65 yr and in whom no clinical or echocardiographic causes are found
  - nonvalvular: not caused by valvular disease, prosthetic heart valves, or valve repair
  - paroxysmal: episodes that terminate spontaneously
  - persistent: AFib sustained for more than 7 d or AFib that terminates only with cardioversion
  - permanent/chronic: continuous AFib that is unresponsive to cardioversion or in which clinical judgement has led to a decision not to pursue cardioversion
  - recurrent: two or more episodes of AFib
  - secondary: caused by a separate underlying condition or event (e.g. MI, cardiac surgery, pulmonary disease, hyperthyroidism)
  - may be associated with thromboembolic events (stroke risk can be assessed by CHADS2 score in nonvalvular AFib, CHADS2-VASC if the former gives a score of 0 or 1)
- initiation
  - single circuit re-entry and/or ectopic foci, mostly arising from the pulmonary veins, act as aberrant generators producing atrial tachycardia (350-600 bpm), which leads to multiple re-entry circuitry (microreentry)
  - impulses conduct irregularly across the atrial myocardium to give rise to fibrillation
  - in most cases, ectopic foci have also been mapped to the pulmonary vein ostia and can be ablated
- maintenance
  - the tachycardia causes atrial structural and electrophysiological remodelling changes that further promote AFib; the longer the patient is in AFib the more difficult it is to convert back to sinus rhythm
- consequences
  - the AV node irregularly filters incoming atrial impulses producing an irregular ventricular response usually <200 bpm, and the tachycardia leads to suboptimal cardiac output
  - fibrillatory conduction of the atria promotes blood stasis increasing the risk of thrombus formation
  - AFib is an important risk factor for stroke
### Table 5. CHADS2 Risk Prediction for Non-Valvular AFib

<td>Diabetes (prior)</td>
<td>4-6</td>
<td>8.5-18.2 (high)</td>
</tr>
<tr>
<td>Stroke/TIA</td>
<td>2</td>
<td></td>
</tr>
</tbody>
</table>

### ECG findings
- no organized P waves due to rapid atrial activity (350-600 bpm) causing a chaotic fibrillatory baseline
- irregularly irregular ventricular response (typically 100-180 bpm), narrow QRS (unless aberrancy or previous BBB)
- wide QRS complexes due to aberrancy may occur following a long-short cycle sequence (“Ashman phenomenon”)
- loss of atrial contraction, thus no “a” wave seen in JVP, no S4 on auscultation

### management (adapted from CCS Atrial Fibrillation Guidelines 2016 & 2018)
- primary goal is symptom control
- major objectives (RACE): all patients with AFib (paroxysmal, persistent, or permanent), should be stratified using a predictive index for stroke risk and for the risk of bleeding, and most patients should receive either an oral anticoagulant or ASA

1. Rate control: β-blockers, diltiazem, verapamil (in patients with heart failure: digoxin, amiodarone)
   - digoxin can be considered as a therapeutic option to achieve rate control in patients whose response to β-blockers and/or calcium channel blockers is inadequate, contraindicated or not tolerated
2. Anticoagulation: use either warfarin or novel oral anticoagulant (NOACs) e.g. apixaban, dabigatran, rivaroxaban, edoxaban to prevent thromboembolism
   - for patients with non-valvular AF (NVAF): oral anticoagulant (OAC) is recommended for most patients aged >65 yr or CHADS2 ≥1
   - ASA 81 mg is recommended only for patients with none of the risk outlined in the CCS algorithm (age <65 and no CHADS2 risk factors) who also have arterial disease (coronary, aortic, or peripheral)
3. Cardioversion (electrical)
   - if AFib <48 h, can usually cardiovert without anticoagulation
   - if AFib >48 h, anticoagulate for 3 wk prior and 4 wk after cardioversion due to risk of unstable intra-atrial thrombus
   - if patient unstable (hypotensive, active angina due to tachycardia, uncontrolled heart failure) should cardiovert immediately
4. Etiology
   - HTN, obesity, sleep apnea, CAD, valvular disease, pericarditis, cardiomyopathy, myocarditis, ASD, post-operative, PE, COPD, thyrotoxicosis, sick sinus syndrome, alcohol (“holiday heart”)
   - may present in young patients without demonstrable disease (“lone AFib”) and in the elderly without underlying heart disease

- studies of patients with AFib suggest that there is no difference in long-term survival when treating patients with a rhythm-control versus rate-control strategy
- many patients with a significant underlying structural heart lesion (e.g. valve disease, cardiomyopathy) will not tolerate AFib well (since may be dependent on atrial kick) and these patients should be cardioverted (chemical or electrical) as soon as possible

### newly discovered AFib
- anticoagulants may be beneficial if high risk for stroke
- if the episode is self-limited and not associated with severe symptoms, no need for antiarrhythmic drugs
- if AFib persists, 2 options:
  1. rate control and anticoagulation (as indicated above)
  2. cardioversion (as indicated above)
- recurrent or permanent AFib
- if episodes are brief or minimally symptomatic, antiarrhythmic drugs may be avoided; rate control and anticoagulation are appropriate
- patients who have undergone at least one attempt to restore sinus rhythm may remain in AFib after recurrence; permanent AFib may be accepted (with rate control and antithrombotics as indicated by CHADS2 score) in certain clinical situations
- if symptoms are bothersome or episodes are prolonged, antiarrhythmic drugs should be used
  - no or minimal heart disease: flecainide, propafenone once proven to have no underlying CAD (may consider exercise stress testing)
6. AV NODAL RE-ENTRANT TACHYCARDIA (AVNRT)
• re-entrant circuit using dual pathways (fast conducting β-fibres and slow conducting α-fibres) within or near the AV node; often found in the absence of structural heart disease
  • cause is commonly idiopathic, although familial AVNRT has been reported
  • sudden onset and offset, patients often describe “neck pounding” and “shirt flapping”
  • fast regular rhythm: rate 150-250 bpm
  • usually initiated by a supraventricular or ventricular premature beat
  • AVNRT accounts for 60-70% of all paroxysmal SVTs
  • retrograde P waves may be seen but are usually lost in the QRS complex
• treatment
  • acute: Valsalva maneuver or carotid sinus pressure technique, adenosine is first choice if unresponsive to vagal maneuvers; if no response, try metoprolol, digoxin, diltiazem, electrical cardioversion if patient hemodynamically unstable (hypotension, angina, or CHF)
  • long-term: 1st line – radiofrequency ablation (>98% cure rate and << 1% complication rate), β-blocker, diltiazem, digoxin; 2nd line – flecainide, propafenone

Wolff-Parkinson-White Syndrome (WPW)
• congenital defect present in 1.5-2/1000 of the general population
• an accessory conduction tract (Bundle of Kent; can be in right or left atrium) abnormally allows early electrical activation of part of one ventricle
• impulses travel at a greater conduction velocity across the Bundle of Kent thereby effectively ‘bypassing’ AV node
• since the ventricles are activated earlier, the ECG shows early ventricular depolarization in the form of initial slurring of the QRS complex – the so-called “delta wave”
• atrial impulses that conduct to the ventricles through both the Bundle of Kent and the normal AV node/His-Purkinje system generate a broad “fusion complex”
• ECG features of WPW
  • PR interval <120 msec
  • delta wave: slurred upstroke of the QRS (the leads with the delta wave vary with site of bypass)
  • widening of the QRS complex due to premature activation
  • secondary ST segment and T wave changes
  • tachyarrhythmias may occur – most often AVRT and AFib

AFib in WPW Patients
• AFib is the index arrhythmia in up to 20% of patients with WPW syndrome
  • usually intermittent rather than persistent or permanent
  • rapid atrial depolarizations in AFib are conducted through the bypass tract which is not able to filter impulses like the AV node can and thus the ventricular rate becomes extremely rapid (>200 bpm) and the QRS complex widens
Arrhythmias

Cardiology and Cardiac Surgery
Toronto Notes 2020

• treatment: electrical cardioversion, IV procainamide, or IV amiodarone
  - do not use drugs that slow AV node conduction (digoxin, β-blockers) as this may cause preferential conduction through the bypass tract and precipitate VF
  - long-term: ablation of bypass tract if possible

AV Re-Entrant Tachycardia
• re-entrant loop via accessory pathway and normal conduction system
• initiated by a premature atrial or ventricular complex
  - orthodromic AVRT: stimulus from a premature complex travels up the bypass tract (V to A) and down the AV node (A to V) with narrow QRS complex (no delta wave because stimulus travels through normal conduction system)
  - comprises 95% of the reentrant tachycardias associated with WPW syndrome
  - antidromic AVRT: more rarely the stimulus goes up the AV node (V to A) and down the bypass tract (A to V); wide and abnormal QRS as ventricular activation is only via the bypass tract
• treatment
  - acute: similar to AVNRT except avoid long-acting AV nodal blockers (e.g. digoxin and verapamil)
  - long-term: for recurrent arrhythmias ablation of the bypass tract is recommended
  - drugs such as flecainide and procainamide can be used

Ventricular Tachyarrhythmias

Premature Ventricular Contraction (PVC) or Ventricular Premature Beat (VPB)
• QRS width >120 msec, no preceding P wave, bizarre QRS morphology
• origin: LBBB morphology of VT = RV origin; RBBB morphology of VT = LV origin
• PVCs may be benign but are usually significant in the following situations:
  - consecutive (≥3 = VT) or multiform (varied origin)
  - PVC falling on the T wave of the previous beat (“R on T phenomenon”): may precipitate ventricular tachycardia or VF
• risk of sustained arrhythmia depends on the clinical situation (i.e. MI, HF), not the PVCs themselves

Accelerated Idioventricular Rhythm
• ectopic ventricular rhythm with rate 50-100 bpm
• more frequently occurs in the presence of sinus bradycardia and is easily overdriven by a faster supraventricular rhythm
• frequently occurs in patients with acute MI or other types of heart disease (i.e. cardiomyopathy, hypertensive, valvular) but it does not affect prognosis and does not usually require treatment

Ventricular Tachycardia (VT)
• 3 or more consecutive ectopic ventricular complexes
  - rate >100 bpm (usually 140-200)
  - ventricular flutter: if rate >200 bpm and complexes resemble a sinusoidal pattern
  - “Sustained VT” if it lasts longer than 30s
  - ECG characteristics: wide regular QRS tachycardia (QRS usually >140 msec)
  - AV dissociation; bizarre QRS pattern
  - also favour Dx of VT: left axis or right axis deviation, nonspecific intraventricular block pattern, monophasic or biphasic QRS in V1 with RBBB, QRS concordance in V1-V6
  - occasionally during VT supraventricular impulses may be conducted to the ventricles generating QRS complexes with normal or aberrant supraventricular morphology (“ventricular capture”) or summation pattern (“fusion complexes”)
  - by themselves, nonsustained VT not dangerous but may indicate higher than usual risk of subsequent sustained VT, especially with structural heart disease

  • monomorphic VT
    - identical complexes with uniform morphology
    - more common than polymorphic VT
    - typically result from intraventricular re-entry circuit, may be idiopathic without any structural heart disease
    - potential causes: chronic infarct related scarring, cardiomyopathies, myocarditis, arrhythmogenic right ventricular dysplasia, idiopathic, drugs (e.g. cocaine), electrolyte disturbances
  • polymorphic VT
    - complexes with constantly changing morphology, amplitude, and polarity
    - more frequently associated with hemodynamic instability due to faster rates (typically 200-250 bpm) vs. monomorphic VT
    - potential causes: acute MI, severe or silent ischemia, and predisposing factors for QT prolongation, dilated cardiomyopathies
• treatment
  - sustained VT (>30 s) is an emergency requiring immediate treatment
  - hemodynamic compromise: electrical cardioversion
  - no hemodynamic compromise: electrical cardioversion, amiodarone, type Ia agents (procainamide, quinidine)
Table 6. Wide Complex Tachycardia: Clues for Differentiating VT vs. SVT with Aberrancy*

*If patient >65 yr and previous MI or structural heart disease, then chance of VT >95%
**May terminate VT in some patients with no structural heart disease

Torsades de Pointes
- A variant of polymorphic VT that occurs in patients with baseline QT prolongation – “twisting of the points”
- Looks like usual VT except that QRS complexes “rotate around the baseline” changing their axis and amplitude
- Ventricular rate >100 bpm, usually 150-300 bpm
  - Usual onset after a post PVC pause (“pause dependent” QT prolongation associated)
- Etiology: predisposition in patients with prolonged QT intervals
  - Congenital long QT syndromes
  - Drugs: e.g. class IA (quinidine), class III (sotalol), phenothiazines (TCAs), erythromycin, quinolones, antihistamines
  - Electrolyte disturbances: hypokalemia, hypomagnesemia
  - Nutritional deficiencies causing above electrolyte abnormalities
- Treatment: IV magnesium, temporary pacing, isoproterenol and correcting the underlying cause of prolonged QT, electrical cardioversion if hemodynamic compromise

Ventricular Fibrillation (VFib)
- Chaotic ventricular arrhythmia, with very rapid irregular ventricular fibrillatory waves of varying morphology
- Terminal event, unless advanced cardiac life-support (ACLS) procedures are promptly initiated to maintain ventilation and cardiac output, and electrical defibrillation is carried out
- Most frequent cause of sudden death
- Refer to ACLS algorithm for complete therapeutic guidelines
Sudden Cardiac Arrest

Definition
- unanticipated, non-traumatic cardiac death in a stable patient which occurs within 1 h of symptom onset; VFib is most common cause

Etiology
- primary cardiac pathology
  - ischemia/MI
  - cardiomyopathy with LV dysfunction
  - severe ventricular hypertrophy
  - HCM
  - AS
  - congenital heart disease e.g. arrhythmogenic right ventricular dysplasia
  - mutations in cardiac ion channels e.g. long QT syndrome, Brugada syndrome

Management
- acute: resuscitate with prompt CPR and defibrillation
- investigate underlying cause (cardiac catheterization, electrophysiologic studies, echocardiography)
- treat underlying cause
- antiarrhythmic drug therapy: amiodarone, β-blockers
- implantable cardioverter defibrillator (ICD)
- refer to ACLS guidelines (see Anesthesia and Perioperative Medicine, A30)

Electrophysiology Studies
- invasive test for the investigation and treatment of cardiac rhythm disorders using intracardiac catheters
- provide detailed analysis of the arrhythmia mechanism and precise site of origin when ECG data are nondiagnostic or unobtainable
- bradyarrhythmias: define the mechanisms of SA node dysfunction and localize site of AV conduction block
- tachyarrhythmias: map for possible ablation or to assess inducibility of VT

Electrical Pacing
- the decision to implant a pacemaker usually is based on symptoms of a bradyarrhythmia or tachycardia in the setting of heart disease

Pacemaker Indications
- SA node dysfunction (most common): symptomatic bradycardia ± hemodynamic instability
- common manifestations include: syncope, presyncope, or severe fatigue
- SA node dysfunction is commonly caused by: intrinsic disease within the SA node (e.g. idiopathic degeneration, fibrosis, ischemia, or surgical trauma), abnormalities in autonomic nervous system function, and drug effects
- AV nodal-infranodal block: Mobitz II, complete heart block

Pacemaker Complications
- complications related to surgical implantation include venous access (pneumothorax, hemothorax, air embolism), pacemaker leads (perforation, malposition), pocket hematomas and infection
- complications specific to the pacemaker include a failure to pace, failure to sense, pulse generator failure, pacemaker syndrome and pacemaker mediated tachycardia

Pacing Techniques
- temporary: transvenous (jugular, subclavian, femoral) or external (transcutaneous) pacing
- permanent: transvenous into RA, apex of RV, or both
- can sense and pace atrium, ventricle, or both
- new generation: rate responsive, able to respond to physiologic demand
- biventricular

Implantable Cardioverter Defibrillators
- sudden cardiac death (SCD) usually results from ventricular fibrillation (VFib), sometimes preceded by monomorphic or polymorphic ventricular tachycardia (VT)
- ICDs detect ventricular tachyarrhythmias and are highly effective in terminating VT/VFib and in aborting SCD
- mortality benefit vs. antiarrhythmics in secondary prevention
- benefit seen in patients with ischemic and non-ischemic cardiomyopathy, depressed left ventricular ejection fraction (LVEF), prolonged QRS
- see Heart Failure, C34 for current treatment recommendations
Catheter Ablation

Techniques
- radiofrequency (RF) ablation: a low-voltage high-frequency form of electrical energy (similar to cautery); RF ablation produces small, homogeneous, necrotic lesions approximately 5-7 mm in diameter and 3-5 mm in depth
- cryoablation: new technology which uses a probe with a tip that can decrease in temperature to -20°C and -70°C which produces small, necrotic lesions similar to RF ablation; when brought to -20°C, the catheter tip reversibly freezes the area; bringing the tip down to -70°C for 5 min permanently scars the tissue
  - advantage: can “test” areas before committing to an ablation
  - disadvantage: takes much longer than RF (5 min per cryoablation vs. 1 min per RF ablation)

Indications
- paroxysmal SVT
  - AVNRT: accounts for more than half of all cases
- accessory pathway (orthodromic reciprocating tachycardia): 30% of SVT
- re-entrant rhythm, with an accessory AV connection as the retrograde limb
- corrected by targeting the accessory pathway
- atrial flutter: re-entry pathway in right atrium
- AFib: primarily pulmonary vein isolation, sometimes with added ablation in the atrial chambers
- ventricular tachycardia: focus arises from the right ventricular outflow tract and less commonly originates in the inferoseptal left ventricle near the apex (note: majority of cases of VT are due to scarring from previous MI and cannot be ablated)

Major Complications
- 1% of patients; death: 0.1-0.2%
- cardiac: high grade AV block requiring permanent pacemaker (less risk with cryoablation), tamponade, pericarditis
- vascular: hematoma, vascular injury, thromboembolism, TIA/stroke
- pulmonary: pulmonary embolism

Ischemic Heart Disease

Epidemiology
- most common cause of cardiovascular morbidity and mortality
- atherosclerosis and thrombosis are the most important pathogenetic mechanisms
- M:F = 2:1 with all age groups included (Framingham study), 8:1 for age <40, 1:1 for age >70
- CHD incidence in women triples shortly after menopause
- peak incidence of symptomatic IHD is age 50-60 (men) and 60-70 (women)
- for primary prevention of ischemic heart disease see Family Medicine, FM7

Hypertension Diabetes Mellitus Smoking Dyslipidemia Rheumatoid Arthritis

Endothelial injury

- Monocyte recruitment
- Enhanced LDL permeability

Monocytes enter into initial space and differentiate into macrophages – LDL is converted into oxidized-LDL (OX-LDL)

Macrophages take up OX-LDL via scavenger receptors to become foam cells (‘fatty streak’ and lipid core of plaque)

Cytokine and growth factor signaling from damaged endothelium and macrophages promote medial smooth muscle cell migration into the intima, proliferation (intimal hyperplasia), and release of matrix to form the fibrous cap of plaque – rupture depends on balance of pro- and anti-proteases, magnitude of necrosis and location of plaque (bifurcation sites are exposed to greater shear stress)

- Calcification
- Plaque rupture
- Hemorrhage into plaque
- Fragmentation
- Wall weakening
- Increased vessel wall rigidity
- Thrombosis
- Lumen narrowing
- Emboli
- Aneurysm

* Major risk factors
§ Modifiable risk factors account for >90% of MIs

### Chronic Stable Angina

#### Definition
- symptom complex resulting from an imbalance between oxygen supply and demand in the myocardium

#### Etiology and Pathophysiology
- factors that decrease myocardial oxygen supply:
  - decreased luminal diameter: atherosclerosis, vasospasm
  - decreased duration of diastole: tachycardia (decreased duration of diastolic coronary perfusion)
  - decreased hemoglobin: anemia
  - decreased SaO2: hypoxemia
  - congenital anomalies
- factors that increase myocardial oxygen demand:
  - increased heart rate: hyperthyroidism
  - increased contractility: hyperthyroidism
  - increased wall stress: myocardial hypertrophy, aortic stenosis

#### Signs and Symptoms
- typical
  1. retrosternal chest pain, tightness or discomfort radiating to left (± right) shoulder/arm/neck/jaw, associated with diaphoresis, nausea, anxiety
  2. predictably precipitated by the "3 Es": exertion, emotion, eating
  3. brief duration, lasting <10-15 min and typically relieved by rest and nitrates
- atypical/probable angina (meets 2 of the above)
- non-cardiac chest pain (meets none or 1 of the above)
- Levine's sign: clutching fist over sternum when describing chest pain
- anginal equivalents: dyspnea, acute LV failure, flash pulmonary edema

#### Clinical Assessment
- history including directed risk factor assessment and physical exam
- labs: HB, fasting glucose, fasting lipid profile
- ECG (at rest and during episode of chest pain if possible)
- CXR (suspected heart failure, valvular disease, pericardial disease, aortic dissection/aneurysm, or signs or symptoms of pulmonary disease)
- stress testing (see Stress Testing, C13) or angiography
- echo
- to assess systolic murmur suggestive of aortic stenosis, mitral regurgitation, and/or HCM
- to assess LV function in patients with Hx of prior MI, pathological Q waves, signs or symptoms of CHF

#### Differential Diagnosis
- see Differential Diagnosis of Common Presentations, C4

#### Treatment of Chronic Stable Angina
1. General Measures
- goals: to reduce myocardial oxygen demand and/or increase oxygen supply
- lifestyle modification (diet, exercise)
- treatment of risk factors: e.g. statins (see Endocrinology, E5, Family Medicine, FM9 for target lipid guidelines), antihypertensives
- pharmacological therapy to stabilize the coronary plaque to prevent rupture and thrombosis

2. Antiplatelet Therapy (first-line therapy)
   - ASA
   - clopidogrel when ASA absolutely contraindicated

3. β-blockers (first-line therapy – improve survival in patients with hypertension)
   - increase coronary perfusion and decrease demand (HR, contractility) and BP (afterload)
   - cardioselective agents preferred (e.g. metoprolol, atenolol) to avoid peripheral effects (inhibition of vasodilation and bronchodilation via β2 receptors)
   - avoid intrinsic sympathomimetics (e.g. acebutolol) which increase demand
4. Nitrates (symptomatic control, no clear impact on survival)
   - decrease preload (venous dilatation) and afterload (arteriolar dilatation), and increase coronary perfusion
   - maintain daily nitrate-free intervals to prevent tolerance (tachyphylaxis)

5. Calcium Channel Blockers (CCBs, second-line or combination)
   - increase coronary perfusion and decrease demand (HR, contractility) and BP (afterload)
   - caution: verapamil/diltiazem combined with β-blockers may cause symptomatic sinus bradycardia or AV block

6. ACE Inhibitors (ACEI, not used to treat symptomatic angina)
   - angina patients tend to have risk factors for CV disease which warrant use of an ACEI (e.g. HTN, DM, proteinuric renal disease, previous MI with LV dysfunction)
   - benefit in all patients at high risk for CV disease (concomitant DM, renal dysfunction, or LV systolic dysfunction)

7. Invasive Strategies
   - revascularization (see Coronary Revascularization, C31 and COURAGE trial sidebar)

VARIANT ANGINA (PRINZMETAL'S ANGINA)
   - myocardial ischemia secondary to coronary artery vasospasm, with or without atherosclerosis
   - uncommonly associated with infarction or LV dysfunction
   - typically occurs between midnight and 8 am, unrelated to exercise, relieved by nitrates
   - typically ST elevation on ECG
   - diagnosed by provocative testing with ergot vasoconstrictors (rarely done)
   - treat with nitrates and CCBs

SYNDROME X
   - typical symptoms of angina but normal angiogram
   - may show definite signs of ischemia with exercise testing
   - thought to be due to inadequate vasodilator reserve of coronary resistance vessels
   - better prognosis than overt epicardial atherosclerosis

Acute Coronary Syndromes

Definition
   - ACS includes the spectrum of unstable angina (UA), NSTEMI, and STEMI; this distinction aids in providing the appropriate therapeutic intervention
   - UA is clinically defined by any of the following:
     - accelerating pattern of pain: increased frequency, increased duration, decreased threshold of exertion, decreased response to treatment
     - angina at rest
     - new-onset angina
     - angina post-MI or post-procedure (e.g. percutaneous coronary intervention [PCI], coronary artery bypass grafting [CABG])
   - MI (STEMI/NSTEMI) is defined by evidence of myocardial necrosis and is diagnosed by a rise/fall of serum markers plus any one of:
     - symptoms of ischemia (chest/upper extremity/mandibular/epigastric discomfort; dyspnea)
     - ECG changes (ST-T changes, new BBB or pathological Q waves)
     - imaging evidence (myocardial loss of viability, wall motion abnormality, or intracoronary thrombus)
     - if biomarker changes are unattainable, cardiac symptoms combined with new ECG changes is sufficient
   - NSTEMI meets criteria for MI without ST elevation or BBB
   - STEMI meets criteria for MI characterized by ST elevation or new BBB

Investigations
   - history and physical
     - note that up to 30% of MIs are unrecognized or "silent" due to atypical symptoms – more common in women, DM, elderly, post-heart transplant (because of denervation)
   - ECG
   - CXR
   - labs
     - serum cardiac biomarkers for myocardial damage (repeat 8 h later) (see Cardiac Biomarkers, C11)
     - CBC, INR/PTT, electrolytes and magnesium, creatinine, urea, glucose, serum lipids
     - draw serum lipids within 24-48 h because values are unreliable from 2-48 d post-MI

MANAGEMENT OF ACUTE CORONARY SYNDROMES

1. General Measures
   - ABCs: assess and correct hemodynamic status first
   - bed rest, cardiac monitoring, oxygen
   - nitroglycerin SL followed by IV
   - morphine IV

2. Initial Management
   - ABCs: assess and correct hemodynamic status first
   - bed rest, cardiac monitoring, oxygen
   - nitroglycerin SL followed by IV
   - morphine IV

3. Investigations
   - history and physical
     - note that up to 30% of MIs are unrecognized or "silent" due to atypical symptoms – more common in women, DM, elderly, post-heart transplant (because of denervation)
   - ECG
   - CXR
   - labs
     - serum cardiac biomarkers for myocardial damage (repeat 8 h later) (see Cardiac Biomarkers, C11)
     - CBC, INR/PTT, electrolytes and magnesium, creatinine, urea, glucose, serum lipids
     - draw serum lipids within 24-48 h because values are unreliable from 2-48 d post-MI

4. Coronary Revascularization
   - PCI as an adjunct in initial management of ACS
   - PCI group had significantly lower rates of subsequent revascularization at 4.6 yr of follow-up (hazard ratio: 1.05; p<0.001)
   - Conclusion: PCI is an adjunct in initial management of ACS

5. Medical Management
   - ACEI/ARB: most effective class in reducing cardiovascular mortality
   - CCBs: 2nd line or combination
   - nitrates: symptomatic control, no clear impact on survival
   - β-blockers: most evidence for benefit in MI and risk reduction
   - statins: highest levels of evidence

6. Secondary Prevention
   - ACEI/ARB: most effective class in reducing cardiovascular mortality
   - CCBs: 2nd line or combination
   - nitrates: symptomatic control, no clear impact on survival
   - β-blockers: most evidence for benefit in MI and risk reduction
   - statins: highest levels of evidence

7. Conclusion
   - ACS includes the spectrum of unstable angina (UA), NSTEMI, and STEMI; this distinction aids in providing the appropriate therapeutic intervention
   - UA is clinically defined by any of the following:
     - accelerating pattern of pain: increased frequency, increased duration, decreased threshold of exertion, decreased response to treatment
     - angina at rest
     - new-onset angina
     - angina post-MI or post-procedure (e.g. percutaneous coronary intervention [PCI], coronary artery bypass grafting [CABG])
   - MI (STEMI/NSTEMI) is defined by evidence of myocardial necrosis and is diagnosed by a rise/fall of serum markers plus any one of:
     - symptoms of ischemia (chest/upper extremity/mandibular/epigastric discomfort; dyspnea)
     - ECG changes (ST-T changes, new BBB or pathological Q waves)
     - imaging evidence (myocardial loss of viability, wall motion abnormality, or intracoronary thrombus)
     - if biomarker changes are unattainable, cardiac symptoms combined with new ECG changes is sufficient
   - NSTEMI meets criteria for MI without ST elevation or BBB
   - STEMI meets criteria for MI characterized by ST elevation or new BBB

8. Acute Coronary Syndromes
   - Definition
     - ACS includes the spectrum of unstable angina (UA), NSTEMI, and STEMI; this distinction aids in providing the appropriate therapeutic intervention
     - UA is clinically defined by any of the following:
       - accelerating pattern of pain: increased frequency, increased duration, decreased threshold of exertion, decreased response to treatment
       - angina at rest
       - new-onset angina
       - angina post-MI or post-procedure (e.g. percutaneous coronary intervention [PCI], coronary artery bypass grafting [CABG])
     - MI (STEMI/NSTEMI) is defined by evidence of myocardial necrosis and is diagnosed by a rise/fall of serum markers plus any one of:
       - symptoms of ischemia (chest/upper extremity/mandibular/epigastric discomfort; dyspnea)
       - ECG changes (ST-T changes, new BBB or pathological Q waves)
       - imaging evidence (myocardial loss of viability, wall motion abnormality, or intracoronary thrombus)
       - if biomarker changes are unattainable, cardiac symptoms combined with new ECG changes is sufficient
     - NSTEMI meets criteria for MI without ST elevation or BBB
     - STEMI meets criteria for MI characterized by ST elevation or new BBB

9. Investigations
   - history and physical
     - note that up to 30% of MIs are unrecognized or "silent" due to atypical symptoms – more common in women, DM, elderly, post-heart transplant (because of denervation)
   - ECG
   - CXR
   - labs
     - serum cardiac biomarkers for myocardial damage (repeat 8 h later) (see Cardiac Biomarkers, C11)
     - CBC, INR/PTT, electrolytes and magnesium, creatinine, urea, glucose, serum lipids
     - draw serum lipids within 24-48 h because values are unreliable from 2-48 d post-MI

10. Coronary Revascularization
    - PCI as an adjunct in initial management of ACS
    - PCI group had significantly lower rates of subsequent revascularization at 4.6 yr of follow-up (hazard ratio: 1.05; p<0.001)
    - Conclusion: PCI is an adjunct in initial management of ACS

11. Medical Management
    - ACEI/ARB: most effective class in reducing cardiovascular mortality
    - CCBs: 2nd line or combination
    - nitrates: symptomatic control, no clear impact on survival
    - β-blockers: most evidence for benefit in MI and risk reduction
    - statins: highest levels of evidence

12. Secondary Prevention
    - ACEI/ARB: most effective class in reducing cardiovascular mortality
    - CCBs: 2nd line or combination
    - nitrates: symptomatic control, no clear impact on survival
    - β-blockers: most evidence for benefit in MI and risk reduction
    - statins: highest levels of evidence

13. Conclusion
    - ACS includes the spectrum of unstable angina (UA), NSTEMI, and STEMI; this distinction aids in providing the appropriate therapeutic intervention
    - UA is clinically defined by any of the following:
      - accelerating pattern of pain: increased frequency, increased duration, decreased threshold of exertion, decreased response to treatment
      - angina at rest
      - new-onset angina
      - angina post-MI or post-procedure (e.g. percutaneous coronary intervention [PCI], coronary artery bypass grafting [CABG])
    - MI (STEMI/NSTEMI) is defined by evidence of myocardial necrosis and is diagnosed by a rise/fall of serum markers plus any one of:
      - symptoms of ischemia (chest/upper extremity/mandibular/epigastric discomfort; dyspnea)
      - ECG changes (ST-T changes, new BBB or pathological Q waves)
      - imaging evidence (myocardial loss of viability, wall motion abnormality, or intracoronary thrombus)
      - if biomarker changes are unattainable, cardiac symptoms combined with new ECG changes is sufficient
    - NSTEMI meets criteria for MI without ST elevation or BBB
    - STEMI meets criteria for MI characterized by ST elevation or new BBB
2. Anti-Platelet and Anticoagulation Therapy

- see also CCS Antiplatelet Guidelines 2012 for details (free mobile apps available on iOS and Android platforms in the CCS app stores)
- ASA chewed
- NSTE MI
  - ticagrelor in addition to ASA or if ASA contraindicated, subcutaneous low molecular weight heparin or IV unfractionated heparin (UFH)
    - LMWH preferable, except in renal failure or if CABG is planned within 24 h
  - clopidogrel used if patient ineligible for ticagrelor
- if PCI is planned: ticagrelor or prasugrel and consider IV GP IIb/IIIa inhibitor (e.g. abciximab)
  - clopidogrel used if patient ineligible for ticagrelor and prasugrel
  - prasugrel contraindicated in those with a history of stroke/TIA, or lower dose is recommended for those >75 yr old or weighing under 60 kg (TRITON-TIMI 38)
- anticoagulation options depend on reperfusion strategy:
  - primary PCI: UFH during procedure; bivalirudin is a possible alternative
  - thrombolysis: LMWH (enoxaparin) until discharge from hospital; can use UFH as alternative because of possible rescue PCI
  - no reperfusion: LMWH (enoxaparin) until discharge from hospital
- continue LMWH or UFH followed by oral anticoagulation at discharge if at high risk for thromboembolic event (large anterior MI, AFib, severe LV dysfunction, CHF, previous DVT or PE, or echo evidence of mural thrombus)

3. β-blockers

- STEMI: contraindications include signs of heart failure, low output states, risk of cardiogenic shock, heart block, asthma or airway disease; initiate orally within 24 h of diagnosis when indicated
- if β-blockers are contraindicated or if β-blockers/nitrates fail to relieve ischemia, non-dihydropyridine calcium channel blockers (e.g. diltiazem, verapamil) may be used as second-line therapy in the absence of severe LV dysfunction or pulmonary vascular congestion (calcium channel blockers do not prevent MI or decrease mortality)

4. Invasive Strategies and Reperfusion Options

- UA/NSTEMI: early coronary angiography ± revascularization if possible is recommended with any of the following high-risk indicators:
  - recurrent angina/ischemia at rest despite intensive anti-ischemic therapy
  - CHF or LV dysfunction
  - hemodynamic instability
  - high (≥3) TIMI risk score (tool used to estimate mortality following an ACS)
  - sustained ventricular tachycardia
  - dynamic ECG changes
  - high-risk findings on non-invasive stress testing
  - PCI within the previous 6 mo
  - repeated presentations for ACS despite treatment and without evidence of ongoing ischemia or high risk features
  - note: thrombolysis is NOT administered for UA/NSTEMI

- STEMI
  - after diagnosis of STEMI is made, do not wait for results of further investigations before implementing reperfusion therapy
  - goal is to re-perfuse artery: thrombolysis ("EMS-to-needle") within 30 min or primary PCI ("EMS-to-balloon") within 90 min (if available)
  - thrombolysis
    - preferred if patient presents ≤12 h of symptom onset, and <30 min after presentation to hospital, has contraindications to PCI, or PCI cannot be administered within 90 min
  - PCI
    - early PCI (≤12 h after symptom onset and <90 min after presentation) improves mortality vs. thrombolysis with fewer intra-cranial hemorrhages and recurrent MIs
    - primary PCI: without prior thrombolytic therapy – method of choice for reperfusion in experienced centres
    - rescue PCI: following failed thrombolytic therapy (diagnosed when following thrombolysis, ST segment elevation fails to resolve below half its initial magnitude and patient still having chest pain)
Figure 36. Reperfusion strategy in STEMI

Table 8. Contraindications for Thrombolysis in STEMI

**Long-Term Management of ACS**

- risk of progression to MI or recurrence of MI or death is highest within 1 mo
- at 1-3 mo after the acute phase, most patients resume a clinical course similar to that in patients with chronic stable coronary disease
- pre-discharge workup: ECG and echo to assess residual LV systolic function
- drugs required in hospital to control ischemia should be continued after discharge in all patients
- other medications for long-term management of ACS are summarized below

1. **General Measures**
   - education
   - risk factor modification

2. **Antiplatelet and Anticoagulation Therapy**
   - see also CCS Antiplatelet Guidelines 2012 for details (free mobile apps available on iOS and Android platforms in the CCS app stores)
   - ECASA 81 mg daily
   - ticagrelor 90 mg twice daily or prasugrel 10 mg daily (at least 1 mo, up to 9-12 mo, if stent placed at least 12 mo)
   - clopidogrel 75 mg daily can be used as alternatives to ticagrelor and prasugrel when indicated
   - ± warfarin x 3 mo if high risk (large anterior MI, LV thrombus, LVEF <30%, history of VTE, chronic AFib)

3. **β-Blockers** (e.g. metoprolol 25-50 mg bid or atenolol 50-100 mg daily)

4. **Nitrates**
   - alleviate ischemia but do not improve outcome
   - use with caution in right-sided MI patients who have become preload dependent

5. **Calcium Channel Blockers** (NOT recommended as first line treatment, consider as alternative to β-blockers)
6. Angiotensin-Converting Enzyme Inhibitors
- prevent adverse ventricular remodelling
- recommended for asymptomatic high-risk patients (e.g. diabetics), even if LVEF >40%
- recommended for symptomatic CHF, reduced LVEF (<40%), anterior MI
- use ARBs in patients who are intolerant of ACEI; avoid combining ACEI and ARB

7. ± Aldosterone Antagonists
- if on ACEI and β-blockers and LVEF <40% and CHF or DM
- significant mortality benefit shown with eplerenone by 30 d

8. Statins (early, intensive, irrespective of cholesterol level; e.g. atorvastatin 80 mg daily)

9. Invasive Cardiac Catheterization if indicated (risk stratification)

### Figure 37. Post-MI risk stratification

#### Prognosis following STEMI
- 5-15% of hospitalized patients will die
  - risk factors
  - infarct size/severity
  - age
  - comorbid conditions
  - development of heart failure or hypotension
- post-discharge mortality rates
  - 6-8% within first year, half of these within first 3 mo
  - 4% per year following first yr
  - risk factors
  - LV dysfunction
  - residual myocardial ischemia
  - ventricular arrhythmias
  - history of prior MI

Coronary Revascularization

PERCUTANEOUS CORONARY INTERVENTION
- interventional cardiology technique aimed at relieving significant coronary stenosis
- main techniques: balloon angioplasty, stenting
- less common techniques: rotational/directional/extraction atherectomy

Indications
- medically refractory angina
- NSTEMI/UA with high risk features (e.g. high TIMI risk score)
- primary/rescue PCI for STEMI

Balloon Angioplasty and Intracoronary Stenting
- coronary lesions dilated with balloon inflation
- major complication is restenosis (approximately 15% at 6 mo), felt to be due to elastic recoil and neointimal hyperplasia
- majority of patients receive intracoronary stent(s) to prevent restenosis
  - bare metal stent (BMS) versus drug-eluting stents: PRAMI trial demonstrated stenting non-culprit lesions results in 14% absolute risk reduction of cardiac death, nonfatal MI, or refractory angina
  - coated with antiproliferative drugs (sirolimus, paclitaxel, everolimus)
  - reduced rate of neointimal hyperplasia and restenosis compared to BMS (5% vs. 20%)
  - complication: late stent thrombosis (5 events per 1000 stents implanted)

Figure 38. AHA ACLS acute coronary syndrome algorithm

Treatment of NSTEMI

BEMOAN
β-blocker
Enoxaparin
Morphine
O2
ASA
Nitrates
Adjunctive Therapies
- ASA and heparin decrease post-procedural complications
- further reduction in ischemic complications has been demonstrated using GPIIb/IIa inhibitors (abciximab, eptifibatide, tirofiban) in coronary angiography and stenting
- following stent implantation
  - dual antiplatelet therapy (ASA and clopidogrel) for 1 mo with BMS or ≥12 mo with DES
  - DAPT study showed benefit of dual antiplatelet therapy beyond 12 mo
- ASA and prasugrel can be considered for those at increased risk of stent thrombosis

Procedural Complications
- mortality and emergency bypass rates <1%
- nonfatal MI: approximately 2-3%

CORONARY ARTERY BYPASS GRAFT SURGERY
- objective of CABG is complete reperfusion of the myocardium

Indications
- CABG
  - ≥50% diameter stenosis in the left main coronary artery
  - ≥70% diameter stenosis in three major coronary arteries
  - ≥70% diameter stenosis in the proximal LAD artery plus one other major coronary artery
  - survivors of sudden cardiac arrest with presumed ischemia-mediated VT caused by significant (≥70% diameter) stenosis in a major coronary artery
  - other
  - ≥70% diameter stenosis in two major coronary arteries (without proximal LAD disease) and evidence of extensive ischemia
  - ≥70% diameter stenosis in the proximal LAD artery and evidence of extensive ischemia
  - multivessel CAD in patients with diabetes
  - LV systolic dysfunction (LVEF ≤35%) and significant multivessel CAD or proximal LAD stenosis where viable myocardium is present in the region of intended revascularization
- PCI
  - PCI if not a CABG candidate
  - STEMI when PCI can be performed more rapidly and safely than CABG
- CABG or PCI
  - one or more significant (≥70% diameter) coronary artery stenosis amenable to revascularization and unacceptable angina despite medical therapy

<tr>
<th>Graft</th>
<th>Occlusion/Patency Rate</th>
<th>Considerations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Saphenous Vein Grafts (SVG)</td>
<td>At 10 yr, 50% occluded, 25% stenotic, 25% angiographically normal</td>
<td>Used when arterial grafts are not available or many grafts are required, such as triple or quadruple bypass</td>
</tr>
<tr>
<td>Left Internal Thoracic/Mammary Artery (LITA/LIMA) (LIMA to LAD)</td>
<td>90-95% patency at 15 yr</td>
<td>Most preferred option because of excellent patency</td>
</tr>
<tr>
<td>Right Internal Thoracic/Mammary Artery (RITA/RIMA)</td>
<td>Pedicled RIMA patency comparable to LIMA</td>
<td>Used in bilateral ITA/IMA grafting</td>
</tr>
<tr>
<td></td>
<td>Free RIMA patency less</td>
<td>Patients receiving bilateral ITAs/IMAs have less risk of recurrent angina, late MI, angiplasty</td>
</tr>
<tr>
<td>Radial Artery (free graft)</td>
<td>85-90% patency at 5 yr</td>
<td>Prone to severe vasospasm post-operatively due to muscular wall</td>
</tr>
<tr>
<td>Right Gastroepiploic Artery</td>
<td>80-90% patency at 5 yr</td>
<td>Primarily used as an in situ graft to bypass the RCA</td>
</tr>
<tr>
<td>Complete Arterial Revascularization</td>
<td>For younger patients (&lt;65 yr of age)</td>
<td>Is preferred due to longer term graft patency</td>
</tr>
<tr>
<td>Redo Bypass Grafting</td>
<td>Operative mortality 2-3x higher than first operation</td>
<td>10% perioperative MI rate</td>
</tr>
<tr>
<td></td>
<td>Reoperation undertaken only in symptomatic patients who have failed medical therapy and in whom angiography has documented progression of the disease</td>
<td>Increased risk with redo-sternotomy secondary to adhesions which may result in laceration to aorta, RV, IMA/ITA, and other bypass grafts</td>
</tr>
</tbody>
</table>
Operative Issues
- left ventricular (LV) function is an important determinant of outcome of all heart diseases
- patients with severe LV dysfunction usually have poor prognosis, but surgery can sometimes dramatically improve LV function
- assess viability of non-functioning myocardial segments in patients with significant LV dysfunction using delayed thallium myocardial imaging, stress echocardiography, PET scanning, or MRI

CABG and Antiplatelet Regimens
- refer to CCS guidelines – 2012 update on antiplatelet therapy – for more information
- prior to CABG, clopidogrel, and ticagrelor should be discontinued for 5 d and prasugrel for 7 d before surgery
- dual antiplatelet therapy should be continued for 12 mo in patients with ACS within 48-72 h after CABG
- ASA (81 mg) continued indefinitely (can be started 6 h after surgery)
- dual antiplatelet therapy should be continued for 12 mo in patients with ACS within 48-72 h after CABG
- patients requiring CABG after PCI should continue their dual antiplatelet therapy as recommended in the post-PCI guidelines

</tr>
</tbody>
</table>

Procedural Complications
- CABG using cardiopulmonary bypass (CPB)
  • stroke and neurocognitive defects (microembolization of gaseous and particulate matter)
  • immunosuppression
  • systemic inflammatory response leading to:
    • myocardial dysfunction
    • renal dysfunction
    • neurological injury
    • respiratory dysfunction
    • coagulopathies

OFF-PUMP CORONARY ARTERY BYPASS SURGERY

Procedure
- avoids the use of CPB by allowing surgeons to operate on a beating heart
- stabilization devices (e.g. Genzyme Immobilizer*) hold heart in place allowing operation while positioning devices (Medtronic Octopus* and Starfish* system) allow the surgeon to lift the beating heart to access the lateral and posterior vessels
- procedure is safe and well tolerated by most patients; however, this surgery remains technically more demanding

Indications/Contraindications
- used in poor candidates for CPB who have: calcified aorta, poor LVEF, severe peripheral vascular disease (PVD), severe COPD, chronic renal failure, coagulopathy, transfusion objections (e.g. Jehovah’s Witness), good target vessels, anterior/lateral wall revascularization, target revascularization in older, sicker patients
- absolute contraindications: hemodynamic instability, poor quality target vessels including intramyocardial vessels, diffusely diseased vessels, and calcified coronary vessels
- relative contraindications: cardiomegaly/CHF, critical left main disease, small distal targets, recent or current acute MI, cardiogenic shock, LVEF <35%

Outcomes
- off-pump coronary artery bypass (OPCAB) surgery decreases in-hospital morbidity (decreased incidence of chest infection, inotropic requirement, supraventricular arrhythmia), blood product transfusion, ICU stay, length of hospitalization, and CK-MB and troponin I levels
- no significant difference in terms of survival at 2 yr, frequency of cardiac events (MI, PCI, CHF, recurrent angina, redo CABG), or medication usage compared to on-pump CABG
Heart Failure

- see also CCS Heart Failure Guidelines 2012 for details (free mobile apps available on iOS and Android platforms in the CCS app stores) as well as the CCS Heart Failure Guidelines Compendium available at CCS.ca

### Congestive Heart Failure

**Low-Output HF**
- **Systolic Dysfunction**
  - Injury and ischemia in myocardium
  - Infarction and inflammation
  - Thin, weak myocardium

- **Diastolic Dysfunction**
  - Infiltration and fibrosis
  - Thick, stiffened myocardium
  - Ineffective ventricular filling

**Increased Cardiac Workload**
- Myocardial stress
- Volume overload
- Pressure overload

**Decompensation**
- Deterioration of heart function
- Heart unable to maintain blood circulation

**Compensation**
- Increased heart rate and myocardial contractility
- Increased blood volume

**Systemic Response**
- Activation of SNS and RAAS activity

**Pathophysiology**
- most common causes are ischemic heart disease, hypertension and valvular heart disease
- myocardial insult causes pump dysfunction/impair filling leading to myocardial remodelling
  - pressure overload (e.g. AS or HTN) leads to compensatory hypertrophy (i.e. concentric remodelling) and eventually interstitial fibrosis
  - volume overload (e.g. aortic insufficiency) leads to dilatation (i.e. eccentric remodelling)
- both processes lead to maladaptive changes contributing to disease process
- results in decreased volume cardiac output resulting in activation of the SNS and RAAS
- Na+ and water retention, which increase preload and afterload, and tachycardia perpetuate the cycle of increasing cardiac demand and thus decompensation

**Figure 39. Congestive heart failure**

© Kelly Speck 2016
Heart Failure with Reduced Ejection Fraction (HFREF: LVEF ≤40%)

- impaired myocardial contractile function → decreased LVEF and SV → decreased CO
- volume overload is the typical phenotype
- findings: apex beat displaced, S3, cardiothoracic ratio >0.5, decreased LVEF, LV dilatation
- causes
  - ischemic (e.g. extensive CAD, previous MI)
  - non-ischemic
    - HTN
    - DM
    - alcohol (and other toxins)
    - myocarditis
    - dilated cardiomyopathy (multiple causes – see Dilated Cardiomyopathy, C40)
    - tachycardia-induced

Heart Failure with Mid-range Ejection Fraction (HFmrEF: LVEF 41-49%)
- epidemiological studies are currently being conducted to better characterize clinical management of this group
- causes: strong association with CAD

Heart Failure with Preserved Ejection Fraction (HFpEF: LVEF ≥50%)

- previously known as “diastolic heart failure”
- concentric remodelling with a “stiff” left ventricle is the typical phenotype
- 1/2 of patients with heart failure have preserved EF; confers similar prognosis to HFREF; more common in the elderly and females
- reduced LV compliance causes increased LV filling pressures, increased LA pressure/volume, and pulmonary congestion
- findings: HTN, apex beat sustained, S4, normal-sized heart on CXR, LVH on ECG/echo, normal EF
- causes
  - transient: ischemia (e.g. CAD, MI)
  - permanent: severe hypertrophy (HTN, aortic stenosis, HCM), restrictive cardiomyopathy (e.g. amyloid), MI

High-Output Heart Failure

- caused by demand for increased cardiac output
- often exacerbates existing heart failure or decompensates a patient with other cardiac pathology
- differential diagnosis: anemia, thiamine deficiency (beriberi), hyperthyroidism, A-V fistula or L-R shunting, Paget’s disease, renal disease, hepatic disease

Precipitants of Symptomatic Exacerbations

- consider natural progression of disease vs. new precipitant
- always search for reversible cause
- differential diagnosis can also be organized as follows:
  - new cardiac insult/disease: MI, arrhythmia, valvular disease
  - new demand on CV system: HTN, anemia, thyrotoxicosis, infection
  - medication non-compliance
  - dietary indiscretion e.g. salt intake
  - obstructive sleep apnea

Investigations

- identify and assess precipitating factors and treatable causes of CHF
- blood work: CBC, electrolytes (including calcium and magnesium), BUN, creatinine, fasting blood glucose, Hba1c, lipid profile, liver function tests, serum TSH ± ferritin, BNP, uric acid
- ECG: look for chamber enlargement, arrhythmia, ischemia/infarction
- CXR: cardiomegaly, pleural effusion, redistribution, Kerley B lines, bronchiolar-alveolar cuffing
- echo: systolic function (LVEF), diastolic function (E/A ratio, E/e’), cardiac dimensions, wall motion abnormalities, right ventricular systolic pressure (from TR jet), valvular disease, pericardial effusion
- radionuclide angiography: LVEF
- myocardial perfusion scintigraphy (thallium or septamibi SPECT)

Acute Treatment of Pulmonary Edema

- treat acute precipitating factors (e.g. ischemia, arrhythmias)
- L – Lasix® (furosemide) 40-500 mg IV
- M – morphine 2-4 mg IV: decreases anxiety and preload (venodilation)
- N – nitroglycerin: topical/IV/SL - use with caution in preload-dependent patients (e.g. right HF or RV infarction) as it may precipitate CV collapse
- O – oxygen: in hypoxemic patients
- P – positive airway pressure (CPAP/BiPAP): decreases preload and need for ventilation when appropriate
- P – position: sit patient up with legs hanging down unless patient is hypotensive

A Validated Clinical and Biochemical Score for the Diagnosis of Acute Heart Failure: the ProBNP Investigation of Dyspnea in the Emergency Department (PRIDE) Acute Heart Failure Score

Brain natriuretic peptide (BNP) is secreted by ventricles due to LV stretch and wall tension. Cardiomyocytes secrete BNP precursor that is cleaved into proBNP. After secretion into ventricles, proBNP is cleaved into the active C-terminal portion and the inactive N-terminal portion of proBNP. The above scoring algorithm developed by Baggish et al. is commonly used. A score of ≥10 has a negative predictive value of 96%, while scores ≥24 had a sensitivity of 96% and specificity of 84% (p<0.001) for the diagnosis of acute heart failure.

New York Heart Association (NYHA)

- Functional Classification of Heart Failure
  - Class I: ordinary physical activity does not cause symptoms of HF
  - Class II: comfortable at rest, ordinary physical activity results in symptoms
  - Class III: marked limitation of ordinary activity; less than ordinary physical activity results in symptoms
  - Class IV: inability to carry out any physical activity without discomfort; symptoms may be present at rest

Five Most Common Causes of CHF

- CAD (60-70%)
- HTN
- Idiopathic (often dilated cardiomyopathy)
- Valvular (e.g. AS, AR, and MR)
- Alcohol (dilated cardiomyopathy)

Precipitants of Heart Failure

- Hypertension (common)
- Endocarditis/environment (e.g. heat wave)
- Anemia
- Rheumatic heart disease and other valvular disease
- Thyrotoxicosis
- Failure to take meds (very common)
- Arthritis (common)
- Infection/Ischemia/Infarction (common)
- Lung problems (PE, pneumoniia, COPD)
- Endocrine (pheochromocytoma, hyperaldosteronism)
- Dietary indiscretions (common)
• in ICU setting or failure of LMNOPP; other interventions may be necessary
  • nitroprusside IV
  • hydralazine PO
  • sympathomimetics
    • dopamine
      – low dose: selective renal vasodilation (high potency D1 agonist)
      – medium dose: inotropic support (medium potency D1 agonist)
      – high dose: increases SVR (low potency D1 agonist), which is undesirable
    • dobutamine
      – β1-selective agonist causing inotropy, tachycardia, hypotension (low dose) or hypertension
      – high dose: most serious side effect is arrhythmia, especially AF
    • phosphodiesterase inhibitors (milrinone)
      – inotropic effect and vascular smooth muscle relaxation (decreased SVR), similar to dobutamine
  • rarely used, but potentially life-saving measures:
    • intra-aortic balloon pump (IABP) - reduces afterload via systolic unloading and improves coronary perfusion via diastolic augmentation
    • left or right ventricular assist device (LVAD/RVAD)
    • cardiac transplant

Long-Term Management
• overwhelming majority of evidence-based management applies to HFREF
• currently no proven pharmacologic therapies shown to reduce mortality in HFPEF; control risk factors for HFPEF (e.g. hypertension)

Conservative Measures
• symptomatic measures: oxygen in hospital, bedrest, elevate the head of bed
• lifestyle measures: diet, exercise, DM control, smoking cessation, decrease alcohol consumption, patient education, sodium and fluid restriction
• multidisciplinary heart failure clinics: for management of individuals at higher risk, or with recent hospitalization

Non-Pharmacological Management
• from CCS guidelines (2017 update)
• cardiac rehabilitation: participation in a structured exercise program for NYHA class I-III after clinical status assessment to improve quality of life (HF-ACTION trial)

Pharmacological Therapy (* indicates initial therapy)
• ACEI/ARB*: Renin-angiotensin-aldosterone blockade
  • ACEI: standard of care – slows progression of LV dysfunction and improves survival
  • all symptomatic patients functional class II-IV
  • all asymptomatic patients with LVEF <40%
  • post-MI
  • angiotensin II receptor blockers
    • second-line to ACEI (if ACEI not tolerated), or as adjunct to ACEI if β-blockers not tolerated
    – combination with ACEI is not routinely recommended and should be used with caution as it may precipitate hyperkalemia, renal failure, the need for dialysis (CHARM, ONTARGET)
  • combination angiotensin II receptor blockers with nephrilysin inhibitors (ARNI) is a new class of medication that has morbidity and mortality benefit over ACEI alone; it has been recommended to replace ACEI or ARBs for patients who have persistent symptoms (PARADIGM-HF)
  • β-blockers*: slow progression and improve survival
    • class I-III with LVEF <40%
    • stable class IV patients
    • carvedilol improves survival in class IV HF (COMET)
    • note: should be used cautiously, titrate slowly because may initially worsen CHF

• Diuretics*: symptom control, management of fluid overload
  • furosemide (40-500 mg daily) for potent diuresis
  • metolazone may be used with furosemide to increase diuresis
  • furosemide, metolazone, and thiazides oppose the hyperkalemia that can be induced by β-blockers, ACEI, ARBs, and aldosterone antagonists

• Mineralocorticoid receptor (aldosterone) antagonists: mortality benefit in symptomatic heart failure and severely depressed ejection fraction
  • spironolactone or eplerenone – for symptomatic heart failure in patients already on ACEI, β-blocker and loop diuretic
  • note: potential for life threatening hyperkalemia
    • monitor K+ after initiation and avoid if Cr >220 µmol/L or K+ >5.2 mmol/L

• Digoxin and cardiac glycosides: digoxin improves symptoms and decreases hospitalizations; no effect on mortality
  • indications: patient in sinus rhythm and symptomatic on ACEI or CHF and AFib
  • patients on digitals glycosides may worsen if these are withdrawn
- **Antiarrhythmic drugs**: for use in CHF with arrhythmia
  - can use amiodarone, β-blocker, or digoxin
- **Anticoagulants**: warfarin for prevention of thromboembolic events
  - prior thromboembolic event or A-Fib, presence of LV thrombus on echo
- **Ivabradine**: selective inhibition of the If current
  - recommended for CV death and hospitalization prevention in patients with HFREF and symptomatic despite treatment with appropriate doses of guideline-directed medical therapy (GDMT), with a resting HR >70 bpm, in sinus rhythm and a prior HF hospitalization within 12 mo
  - greatest benefit likely with marked LV enlargement, mitral regurgitation, QRS >150 msec
- **Hydralazine plus isosorbide dinitrate**: symptom control and mortality benefit in black patients with symptomatic HFREF despite GDMT
  - recommended also for HFREF patients with drug intolerance to ACEI and ARB

**Procedural Interventions**
- resynchronization therapy: symptomatic improvement with biventricular pacemaker
  - consider if QRS >130 msec, LVEF <35%, and persistent symptoms despite optimal therapy
  - greatest benefit likely with marked LV enlargement, mitral regurgitation, QRS >150 msec
- ICD: mortality benefit in 1º prevention of sudden cardiac death
  - prior MI, optimal medical therapy, LVEF <30%, clinically stable
  - prior MI, non-sustained VT, LVEF 30–40%, EPS inducible VT
- LVAD/RVAD (see Ventricular Assist Devices, C38)
- cardiac transplantation (see Cardiac Transplantation, C38)
- valve repair if patient is surgical candidate and has significant valve disease contributing to CHF (see Valvular Heart Disease, C42)

**Figure 40. Ivabradine mechanism of action**

**Procedural Interventions**
- resynchronization therapy: symptomatic improvement with biventricular pacemaker
  - consider if QRS >130 msec, LVEF <35%, and persistent symptoms despite optimal therapy
  - greatest benefit likely with marked LV enlargement, mitral regurgitation, QRS >150 msec
- ICD: mortality benefit in 1º prevention of sudden cardiac death
  - prior MI, optimal medical therapy, LVEF <30%, clinically stable
  - prior MI, non-sustained VT, LVEF 30–40%, EPS inducible VT
- LVAD/RVAD (see Ventricular Assist Devices, C38)
- cardiac transplantation (see Cardiac Transplantation, C38)
- valve repair if patient is surgical candidate and has significant valve disease contributing to CHF (see Valvular Heart Disease, C42)

**Figure 41. Effect of heart failure treatment on the Frank-Starling curve**

**Hypotension**
- vasodilator
  - nitrates
- diuretic or venodilator
  - nitrates

**Heart Failure**

**NORMAL**
- A = diuretic or venodilator
- B = inotrope + ACEI

**HEART FAILURE + TREATMENT**
- I = diuretics
- D = ACEI

**HEART FAILURE**
- Failing heart

**Chronic Treatment of CHF**
- ACEi* 
- β-blockers* 
- Mineralocorticoid receptor antagonists*
  - Diuretic
  - β-Blocker
  - Antiarhythmic
  - Anticoagulant

*Mortality benefit

**Ivabradine and Outcomes in Chronic Heart Failure (SHIFT): A Randomized Placebo-Controlled Study**

**Purpose**: To establish the association between New York Heart Association Classes and increased mortality and hospitalization in patients with heart failure and preserved systolic function.

**Methods**: Retrospective follow-up study (median 38.5 mo) of 988 patients with heart failure with ejection fraction >45%. Estimated risks of various outcomes using Cox proportional hazard models.

**Results**: Adjusted hazard ratio for all-cause mortality for NYHA class II, III, IV patients was 1.54, 2.56, and 8.46, respectively. Adjusted hazard ratio for all-cause hospitalization for NYHA class II, III, IV patients was 1.23, 1.71, and 3.4, respectively.

**Conclusions**: Higher NYHA classes were associated with poorer outcomes in patients with heart failure and preserved systolic function. Proportions of NYHA I, II, III, and IV patients who died of all causes during the study were 14.3%.
Sleep-Disordered Breathing

- patients with CHF can have sleep disturbances; 40% of patients have central sleep apnea with Cheyne-Stokes breathing and 11% of patients have obstructive sleep apnea
- associated with a worse prognosis and greater LV dysfunction
- nasal continuous positive airway pressure (CPAP) is effective in treating symptoms of sleep apnea with secondary beneficial effects in cardiac function and symptoms

Cardiac Transplantation

- treatment for end-stage heart disease; due to ischemic or non-ischemic cardiomyopathy
- worldwide 1 yr survival is 85-90%, 5 yr survival about 60%, annual mortality rate of 4%
- matching is according to blood type, body size and weight (should be within 25%), and HLA tissue matching (if time allows)

Indications for Surgery

- severe cardiac disability despite maximal medical therapy (e.g. recurrent hospitalizations for CHF; NYHA III or IV, peak metabolic oxygen consumption <14 mL/kg/min in absence of β-blocker)
- symptomatic cardiac ischemia refractory to conventional treatment (e.g. unstable angina not amenable to CABG or PCI with LVEF <30%; recurrent, symptomatic ventricular arrhythmias)
- cardiogenic shock requiring IV inotropic agents or mechanical circulatory support to sustain organ perfusion
- exclusion of all surgical alternatives to cardiac transplantation

Contraindications (*indicates absolute contraindications)

- incurable malignancy*
- major systemic illness*
- irreversible major organ disease*
- active systemic infection
- obesity
- irreversible pulmonary HTN (pulmonary vascular resistance [PVR] >6 Wood units)*
- severe COPD (FEV1 <1 L)*
- active drug addiction or alcoholism*

Prerequisites

- psychosocial stability
- medically compliant and motivated

Complications

- rejection
  - common, <5% have serious hemodynamic compromise
  - gold standard to detect rejection: endomyocardial biopsy
  - risk of acute rejection is greatest during the first 3 mo after transplant
- infection
  - leading cause of morbidity and mortality after cardiac transplantation
  - risk peaks early during the first few months after transplantation and then declines to a low persistent rate
- allograft vasculopathy
  - approximately 50% develop graft vasculopathy within 10 yr of transplantation
  - most common cause of late death following transplantation
- malignancy
  - develops in 15% of cardiac transplant recipients due to immunosuppressive medication
  - second most common cause of late death following transplantation
- cutaneous neoplasms most common, followed by non-Hodgkin’s lymphoma and lung cancer
- immunosuppressive medication side effects (prednisone, cyclosporine, tacrolimus, sirolimus)

Ventricular Assist Devices

- work to unload the ventricle while maintaining output; also results in decreased myocardial oxygen consumption permitting recovery of the myocardium that is not irreversibly injured
- can support the left (LVAD), right (RVAD), or both ventricles (BiVAD)
- indications:
  - bridge to transplantation, bridge to decision (for transplant), or long term permanent therapy (“destination therapy”)
  - post-operative mechanical support when unable to separate from cardiopulmonary bypass despite inotropic and intra-aortic balloon pump (IABP) support
  - IABP is a catheter based device inserted into the femoral artery and advanced to the descending aorta that decreases myocardial O2 demand and increases blood flow to coronary arteries
  - inflation of the balloon occurs during diastole to increase ascending aorta and coronary artery perfusion pressure; deflation occurs at systole to reduce intra-aortic pressure thus reducing afterload
  - cardiogenic shock
Myocardial Disease

Definition of Cardiomyopathy
- intrinsic or primary myocardial disease not secondary to congenital, hypertensive, coronary, valvular, or pericardial disease
- functional classification: dilated, hypertrophic, or restrictive
- LV dysfunction 2nd to MI, often termed "ischemic cardiomyopathy", is not a true cardiomyopathy (i.e. primary myocardial disorder) since the primary pathology is obstructive CAD

Myocarditis

Definition
- inflammatory process involving the myocardium ranging from acute to chronic; an important cause of dilated cardiomyopathy

Etiology
- idiopathic
- infectious
  - viral (most common): parvovirus B19, influenza, coxsackie B, echovirus, poliovirus, HIV, mumps
  - bacterial: S. aureus, C. perfringens, C. diphtheriae, Mycoplasma, Rickettsia
  - fungi
  - spirochetal (Lyme disease – Borrelia burgdorferi)
  - Chagas disease (Trypanosoma cruzi), toxoplasmosis
  - toxic: catecholamines, chemotherapy, cocaine
  - hypersensitivity/eosinophilic: drugs (e.g. antibiotics, diuretics, lithium, clozapine), insect/snake bites
  - systemic diseases: collagen vascular diseases (e.g. SLE, rheumatoid arthritis), sarcoidosis, autoimmune
  - other: giant cell myocarditis, acute rheumatic fever

Signs and Symptoms
- constitutional symptoms
- acute CHF: dyspnea, tachycardia, elevated JVP
- chest pain: due to pericarditis or cardiac ischemia
- arrhythmias
- systemic or pulmonary emboli
- pre-syncpe/syncope/sudden death

Investigations
- ECG: non-specific ST-T changes ± conduction defects
- blood work
  - increased CK, troponin, LDH, and AST with acute myocardial necrosis ± increased WBC, ESR, ANA, rheumatoid factor, complement levels
  - blood culture, viral titres, and cold agglutinins for Mycoplasma
- CXR: enlarged cardiac silhouette
- echo: dilated, hypokinetic chambers, segmental wall motion abnormalities
- cardiovascular magnetic resonance: functional and morphological abnormalities as well as tissue pathology (gadolinium enhancement)
- myocardial biopsy

Management
- supportive care
- restrict physical activity
- treat CHF
- treat arrhythmias
- anticoagulation
- treat underlying cause if possible

Prognosis
- often unrecognized and may be self-limited
- myocarditis treatment trial showed 5 yr mortality between 25-50%
- giant cell myocarditis, although rare can present with fulminant CHF and be rapidly fatal, with 5 yr mortality >80%
- sudden death in young adults
- may progress to dilated cardiomyopathy
Dilated Cardiomyopathy

Definition
- unexplained dilation and impaired systolic function of one or both ventricles

Etiology
- idiopathic (presumed viral or idiopathic) ~50% of DCM
- alcohol
- familial/genetic
- uncontrolled tachycardia (e.g. persistent rapid AFib)
- collagen vascular disease: SLE, polyarteritis nodosa, dermatomyositis, progressive systemic sclerosis
- infectious: viral (coxackie B, HIV), Chagas disease, Lyme disease, Rickettsial diseases, acute rheumatic fever, toxoplasmosis
- neuromuscular disease: Duchenne muscular dystrophy, myotonic dystrophy, Friedreich's ataxia
- metabolic: uremia, nutritional deficiency (thiamine, selenium, carnitine)
- endocrine: hyper/hypothyroidism, DM, pheochromocytoma
- peripartum
- toxic: cocaine, heroin, organic solvents
- drugs: chemotherapies (doxorubicin, cyclophosphamide), anti-retrovirals, chloroquine, clozapine, TCA
- radiation

Signs and Symptoms
- may present as:
  - CHF
  - systemic or pulmonary emboli
  - arrhythmias
  - sudden death (major cause of mortality due to fatal arrhythmia)

Investigations
- blood work: CBC, electrolytes, Cr, bicarbonate, BNP, CK, troponin, LFTs, TSH, TIBC
- ECG: variable ST-T wave abnormalities, poor R wave progression, conduction defects (e.g. BBB), arrhythmias (e.g. non-sustained VT)
- CXR: global cardiomegaly (i.e. globular heart), signs of CHF, pleural effusion
- echo: chamber enlargement, global hypokinesis, depressed LVEF, MR and TR, mural thrombi
- endomyocardial biopsy: not routine, used to rule out a treatable cause
- coronary angiography: in selected patients to exclude ischemic heart disease

Management
- treat underlying disease: e.g. abstinence from alcohol
- treat CHF: see Heart Failure, C34
- thromboembolism prophylaxis: anticoagulation with warfarin
- indicated for: AFib, history of thromboembolism or documented thrombus
- treat symptomatic or serious arrhythmias
- immunize against influenza and S. pneumoniae
- consider surgical options (e.g. LVAD, transplant, volume reduction surgery) in appropriate candidates
  with severe, drug refractory disease
- consider ICD among patients with a LVEF <30%

Prognosis
- depends on etiology
- better with reversible underlying cause, worst with infiltrative diseases, HIV, drug-induced
- cause of death usually CHF (due to pump failure) or sudden death 2° to ventricular arrhythmias
- systemic emboli are significant source of morbidity
- 20% mortality in 1st yr, 10% per year thereafter

Hypertrophic Cardiomyopathy

Definition
- defined as unexplained ventricular hypertrophy
- various patterns of HCM are classified, but most causes involve pattern of septal hypertrophy

Etiology and Pathophysiology
- histopathologic features include myocyte disarray, myocyte hypertrophy, and interstitial fibrosis
- cause is felt to be a genetic defect involving one of the cardiac sarcomeric proteins (>400 mutations associated with autosomal dominant inheritance, incomplete penetrance)
- prevalence of 1/500-1/1000 in general population
- generally presents in early adulthood

Hemodynamic Classification
- hypertrophic obstructive cardiomyopathy (HOCM): dynamic LV outflow tract (LVOT) obstruction, either at rest or with provocation, defined as LVOT gradient of at least 30 mmHg
  - dynamic i.e. obstruction (and the murmur) is reduced with maneuvers that increase preload and augmented with maneuvers that reduce preload

Abnormal Labs in DCM
- High BNP
- High Cr
- High LFTs
- Low bicarbonate
- Low Na+
• non-obstructive HCM: no LVOT obstruction
• many patients have diastolic dysfunction (impaired ventricular filling secondary to LV hypertrophy which decreases compliance)

**Signs and Symptoms**
• clinical manifestations: asymptomatic (common, therefore screening is important), shortness of breath on exertion (SOBOE), angina, presyncope/syncope (due to LV outflow obstruction or arrhythmia), CHF, arrhythmias, SCD
• pulse: rapid upstroke, “spike and dome” pattern in carotid pulse (in HCM with outflow tract obstruction)
• precordial palpation: PMI localized, sustained, double impulse, ‘triple ripple’ (triple apical impulse in HOCM), LV lift
• precordial auscultation: normal or paradoxically split S2, S4, harsh systolic diamond-shaped murmur at LLSB or apex, enhanced by squat to standing or Valsalva (murmur secondary to LVOT obstruction as compared to AS), often with pansystolic murmur due to mitral regurgitation

**Investigations**
• ECG/Holter monitor: LVH, high voltages across precordium, prominent Q waves (lead I, aVL, V5, V6), tall R wave in V1, P wave abnormalities
• transthoracic echocardiography and echo-Doppler study: asymmetric septal hypertrophy (less commonly apical), systolic anterior motion (SAM) of mitral valve and MR; LVOT gradient can be estimated by Doppler measurement
• genetic studies (± magnetic resonance imaging) can be helpful when echocardiography is inconclusive for diagnosis
• cardiac catheterization (only when patient being considered for invasive therapy)

**Management**
• avoid factors which increase obstruction (e.g. volume depletion)
  ▪ avoidance of all competitive sports
• treatment of obstructive HCM
  ▪ medical agents: β-blockers, disopyramide, verapamil (started only in monitored setting), phenylephrine (in setting of cardiogenic shock)
  ▪ avoid nitrates, diuretics, and ACEI as they increase LVOT gradient and worsen symptoms
• patients with obstructive HCM and drug-refractory symptoms
  ▪ surgical myectomy
  ▪ alcohol septal ablation - percutaneous intervention that ablates the hypertrophic septum with 100% ethanol via the septal artery
  ▪ dual chamber pacing (rarely done)
• treatment of patients at high risk of sudden death: ICD
• first-degree relatives (children, siblings, parents) of patients with HCM should be screened (physical, ECG, 2D echo) every 12-18 mo during adolescence, then serially every 5 yr during adulthood

**Prognosis**
• potential complications: AFib, VT, CHF, sudden cardiac death (1% risk/yr; most common cause of SCD in young athletes)
  ▪ major risk factors for sudden death (consider ICD placement)
  ▪ history of survived cardiac arrest/sustained VT
  ▪ family history of multiple premature sudden deaths
  ▪ other factors associated with increased risk of sudden cardiac death
    ▪ syncope (presumed to be arrhythmic in origin)
    ▪ non-sustained VT on ambulatory monitoring
    ▪ marked ventricular hypertrophy (maximum wall thickness ≥30 mm)
    ▪ abnormal BP in response to exercise (in patients <40 yr old with HCM)

**Restrictive Cardiomyopathy**

**Definition**
• impaired ventricular filling with preserved systolic function in a non-dilated, non-hypertrophied ventricle secondary to factors that decrease myocardial compliance (fibrosis and/or infiltration)

**Etiology**
• infiltrative: amyloidosis, sarcoidosis
• non-infiltrative: scleroderma, idiopathic myocardial fibrosis
• storage diseases: hemochromatosis, Fabry’s disease, Gaucher’s disease, glycogen storage diseases
• endomyocardial
  ▪ endomyocardial fibrosis, Loeffler’s endocarditis, or eosinophilic endomyocardial disease
  ▪ radiation heart disease
• carcinoid syndrome (may have associated tricuspid valve or pulmonary valve dysfunction)

**Clinical Manifestations**
• CHF (usually with preserved LV systolic function), arrhythmias
• elevated JVP with prominent x and y descents, Kussmaul’s sign
• S3, S4, MR, TR
• thromboembolic events
Investigations
- ECG: low voltage, non-specific, diffuse ST-T wave changes ± non-ischemic Q waves
- CXR: mild cardiac enlargement
- Echo: LVEF, RAE: specific Doppler findings with no significant respiratory variation
- cardiac catheterization: increased end-diastolic ventricular pressures
- endomyocardial biopsy: to determine etiology (especially for infiltrative RCM)

Management
- exclude constrictive pericarditis
- treat underlying disease: control HR, anticoagulate if AFib
- supportive care and treatment for CHF, arrhythmias
- cardiac transplant: might be considered for CHF refractory to medical therapy

Prognosis
- depends on etiology

Valvular Heart Disease

see the 2017 AHA/ACC Focused Update of the 2014 AHA/ACC Guideline for the Management of Patients With Valvular Heart Disease. JACC Jul 11;70(2):252-289 for details

Infective Endocarditis

see Infectious Diseases, ID13

American Heart Association (AHA) 2007 guidelines recommend IE prophylaxis
- only for patients with:
  - prosthetic valve material
  - past history of IE
  - certain types of congenital heart disease
  - cardiac transplant recipients who develop valvulopathy
- only for the following procedures:
  - dental
  - respiratory tract
  - procedures on infected skin/skin structures/MSK structures
  - not GI/GU procedures specifically

Rheumatic Fever

see Pediatrics, P56

Prognosis
- acute complications: myocarditis (DCM/CHF), conduction abnormalities (sinus tachycardia, AFib), valvulitis (acute MR), acute pericarditis (not constrictive pericarditis)
- chronic complications: rheumatic valvular heart disease – fibrous thickening, adhesion, calcification of valve leaflets resulting in stenosis/regurgitation, increased risk of IE ± thromboembolism
- onset of symptoms usually after 10-20 yr latency from acute carditis of rheumatic fever
- mitral valve most commonly affected

Valve Repair and Valve Replacement

- indication for valve repair or replacement depends on the severity of the pathology; typically recommended when medical management has failed to adequately improve the symptoms or reduce the risk of morbidity and mortality
- pathologies that may require surgical intervention include congenital defects, infections, rheumatic heart disease as well as a variety of valve diseases associated with aging (i.e. degenerative valve lesions)
- valve repair: surgical valvuloplasty (commissurotomy, annuloplasty), chordae tendineae repair, tissue patch
- valve replacement: typically for aortic or mitral valves only; mitral valve repair is favoured in younger individuals (and patients with mitral valve prolapse with severe mitral regurgitation)
- percutaneous techniques are being established to replace or repair valves
- decision between mechanical vs. bioprosthetic prosthesis for patients 50-70 yr old remains uncertain as valve techniques evolve

Choice of Valve Prosthesis

Mitral Valve Repair vs. Replacement for Severe Ischemic Mitral Regurgitation

NEJM 2014;370:23-32

Purpose: Ischemic mitral regurgitation is associated with significant mortality risk. The purpose of this study was to compare the effectiveness and safety of repairing versus replacing the mitral valve in patients with severe chronic ischemic mitral regurgitation.

Study Design: RCT with 251 patients with severe ischemic mitral regurgitation were randomly assigned to mitral valve repair or chordal-sparing replacement. The primary endpoint was the left ventricular end-systolic volume index (LVESVI) at 12 mo.

Results: There were no significant between-group differences in LVESVI, in the rate of major adverse cardiac or cerebrovascular events, in functional status, or in quality of life at 12 mo. The rate of moderate or severe mitral regurgitation recurrence at 12 mo was significantly higher in the repair group than in the replacement group (32.6% vs. 2.3%, respectively).

Conclusions: No significant difference in left ventricular reverse modeling or survival at 12 mo between patients who underwent mitral valve repair or replacement. Replacement provided more durable correction of mitral regurgitation, but there were no significant differences in clinical outcomes.

### Table 16. Valvular Heart Disease (continued)

#### Mitral Stenosis (MS)

**Etiology**  
Rheumatic disease most common cause, congenital (rare)

**Definition**  
Severe MS is mitral valve area (MVA) <1.5 cm²

**Pathophysiology**  
- MS → fixed CO and LAE → increased LA pressure → pulmonary vascular resistance and CHF, worse with AFib (no atrial kick), tachycardia (decreased atrial emptying time) and pregnancy (increased preload)

**Symptoms**  
- SDB on exertion, orthopnea, fatigue, palpitations, peripheral edema, malar flush, pinched and blue facies (severe MS)

**Physical Exam**  
- AFib, no “a” wave on JVP, left parasternal lift, palpable diastolic thrill at apex
- Auscultation: mid-diastolic rumble at apex, best heard with bell in left lateral decubitus position following exertion, loud S1, OS following loud P2 (heard best during expiration), long diastolic murmur, and short A2-OS interval correlate with worse MS
- Auscultation: mid-diastolic rumble at apex, best heard with bell in left lateral decubitus position following exertion, loud S1, OS following loud P2 (heard best during expiration), long diastolic murmur, and short A2-OS interval correlate with worse MS

**Investigations**  
- ECG: NSR/A fib, LAE (P mitrale), RVH, RAD
- CXR: LVH, LAE, CHF, mitral valve calcification
- Echo/TTE: shows restricted opening of mitral valve
- Cath: indicated in concurrent CAD if >40 yr (male) or >50 yr (female)

**Treatment**  
- Avoid exertion, fever (increased LA pressure), treat AFib and CHF, increase diastolic filling time (β-blockers, digitalis)
- Surgery if: NYHA class III-IV CHF and failure of medical therapy

**Invasive Options**  
- Percutaneous balloon valvuloplasty: young rheumatic pts and good leaflet morphology
- Annuloplasty (i.e. repair, rarely replacement)
- Surgery if: only if other surgery required (e.g. mitral valve replacement)

**Advantage of repair:** low rate of endocarditis, no anticoagulation, less chance of re-operation

#### Mitral Regurgitation (MR)

**Etiology**  
Mitral valve prolapse, congenital cleft leaflets, LV dilatation/aneurysm (CHF, DCM, myocardiitis), IE abscess, Marfan’s syndrome, HOCM, acute MI, myxoma, mitral valve annulus calcification, chordae/papillary muscle trauma/ischemia/rupture (acute), rheumatic disease

**Pathophysiology**  
- Reduced CO → increased LV and LA pressure → LV and LA dilatation → CHF and pulmonary HTN

**Symptoms**  
- Dyspnea, PND, orthopnea, palpitations, peripheral edema

**Physical Exam**  
- Displaced hyperdynamic apex, left parasternal lift, apical thrill
- Auscultation: holosystolic murmur at apex, radiating to axilla ± mid-diastolic rumble, loud S2 (if pulmonary HTN), S3

**Investigations**  
- ECG: LAE, left atrial delay (bifid P waves), ± LVH
- CXR: LVH, LAE, pulmonary venous HTN
- Echo: etiology and severity of MR, LV function, leaflets

**Surgical Options**  
- Valve repair: 70% of pts with MR and myxomatous mitral valve prolapse – annuloplasty rings, leaflet repair, chordae transfers/shorten/replacement
- Valve replacement: failure of repair, heavily calcified annulus
- Advantage of repair: low rate of endocarditis, no anticoagulation, less chance of re-operation

#### Tricuspid Stenosis (TS)

**Etiology**  
Rheumatic disease, congenital, carcinoid syndrome, fibroelastosis; usually accompanied by MS (in RHD)

**Pathophysiology**  
- Increased RA pressure → right heart failure → decreased CO and fixed on exertion

**Symptoms**  
- Peripheral edema, fatigue, palpitations

**Physical Exam**  
- Prominent “s” waves in JVP, +ve abdominojugular reflux, Kussmaul’s sign, diastolic rumble 4th left intercostal space

**Investigations**  
- ECG: RA ECG: CXR: diastolic WT without pulmonary artery enlargement
- Echo: diagnostic

**Treatment**  
- Preload reduction (diuretics), slow HR
- Surgery if: only if other surgery required (e.g. mitral valve replacement)

**Surgical Options**  
- Valve Replacement:
  - if severely diseased valve
  - bioprosthesis preferred

#### Tricuspid Regurgitation (TR)

**Etiology**  
RV dilatation, IE (particularly due to IV drug use), rheumatic disease, congenital (Ebstein anomaly), carcinoid

**Pathophysiology**  
RV dilatation → TR further RV dilatation → right heart failure

**Symptoms**  
- Peripheral edema, fatigue, palpitations

**Physical Exam**  
- “cv” waves in JVP, +ve abdominojugular reflux, holosystolic murmur at LLSB accentuated by inspiration, left parasternal lift

**Investigations**  
- ECG: RAE, RVH, A fib
- CXR: RV enlargement
- Echo: diagnostic

**Treatment**  
- Preload reduction (diuretics)
- Surgery if: only if other surgery required (e.g. mitral valve replacement)

**Surgical Options**  
- Annuloplasty (i.e. repair, rarely replacement)
Table 16. Valvular Heart Disease (continued)

### Pulmonary Stenosis (PS)

**Etiology**
- Usually congenital, rheumatic disease
- Rare, carcinoid syndrome

**Pathophysiology**
- Increased RV pressure → RV hypertrophy → right heart failure

**Symptoms**
- Chest pain, syncope, fatigue, peripheral edema

**Physical Exam**
- Systolic murmur at 2nd left intercostal space accentuated by inspiration, pulmonary ejection click, right-sided S4

**Investigations**
- ECG: RVH
- CXR: prominent pulmonary arteries enlarged RV
- Echo: diagnostic

**Treatment**
- Balloon valvuloplasty if severe symptoms
- Percutaneous or open balloon valvuloplasty

### Pulmonary Regurgitation (PR)

**Etiology**
- Pulmonary HTN, IE, rheumatic disease, tetralogy of Fallot (post-repair)

**Pathophysiology**
- Increased RV volume → increased wall tension → RV hypertrophy → right heart failure

**Symptoms**
- Chest pain, syncope, fatigue, peripheral edema

**Physical Exam**
- Early diastolic murmur at LL SB, Graham Steell (diastolic) murmur 2nd and 3rd left intercostal space increasing with inspiration

**Investigations**
- ECG: RVH
- CXR: prominent pulmonary arteries if pulmonary HTN; enlarged RV
- Echo: diagnostic

**Treatment**
- Rarely requires treatment; valve replacement (rarely done)

**Surgical Options**
- Pulmonary valve replacement

### Mitral Valve Prolapse (MVP)

**Etiology**
- Myxomatous degeneration of chordae, thick, bulky leaflets that crowd orifice, associated with Marfan’s syndrome, pectus excavatum, straight back syndrome, other MSK abnormalities; <3% of population

**Pathophysiology**
- Mitral valve displaced into LA during systole; no causal mechanisms found for symptoms

**Symptoms**
- Prolonged, stabbing chest pain, dyspnea, anxiety/panic, palpitations, fatigue, presyncope

**Physical Exam**
- Auscultation: mid-systolic click (due to billowing of mitral leaflet into LA; tensing of chordae, thick, bulky leaflets that crowd orifice, associated with Marfan’s syndrome, pectus excavatum, straight back syndrome, other MSK abnormalities; <3% of population)

**Investigations**
- ECG: non-specific ST-T wave changes, paroxysmal SVT, ventricular ectopy
- Echo: systolic displacement of thickened mitral valve leaflets into LA

**Treatment**
- Asymptomatic: no treatment; reassurance
- Symptomatic: β-blockers and avoidance of stimulants (caffeine) for significant palpitations, anticoagulation if AFib

**Surgical Options**
- Mitral valve surgery (repair favoured over replacement) if symptomatic and significant MR

---

**Figure 42. Hemodynamics of aortic stenosis**

Stenosis across the aortic valve results in the generation of a significant pressure gradient between the left ventricle and the aorta and a crescendo-decrescendo murmur during systolic contraction. The stenosis decreases the intensity of aortic valve closure hence diminishing S2.

**Figure 43. Hemodynamics of aortic regurgitation**

Regurgitation across the aortic valve during diastole causes the aortic pressure to rapidly decrease and a decrescendo murmur can be heard at the onset of diastole (after S2 is audible). The presence of regurgitant blood from the aorta increases left-ventricular end-diastolic volume.

**Figure 44. Hemodynamics of acute mitral regurgitation**

During systolic contraction, blood regurgitates from the left ventricle into the left atrium across the incompetent mitral valve resulting in an audible holosystolic murmur between S1 and S2. The portion of left ventricular end-diastolic volume that regurgitates into the left atrial myocardium increases left atrial pressures resulting in a tall V-wave (in the JVP).
Pericardial Disease

Acute Pericarditis

**Etiology of Pericarditis/Pericardial Effusion**
- idiopathic is most common: presumed to be viral
- infectious
  - viral: Coxackie virus A, B (most common), echovirus
  - bacterial: *S. pneumoniae, S. aureus*
  - TB
- fungal: histoplasmosis, blastomycosis
- post-MI: acute (direct extension of myocardial inflammation, 1-7 d post-MI), Dressler’s syndrome (autoimmune reaction, 2-8 wk post-MI)
- post-cardiac surgery (e.g. CABG), other trauma
- metabolic: uremia (common), hypothyroidism
- neoplasm: Hodgkin’s, breast, lung, renal cell carcinoma, melanoma
- collagen vascular disease: SLE, polyarteritis, rheumatoid arthritis, scleroderma
- vascular: dissecting aneurysm
- other: drugs (e.g. hydralazine), radiation, infiltrative disease (e.g. sarcoid), vaccination (e.g. smallpox)

**Signs and Symptoms**
- diagnostic triad: chest pain, friction rub, and ECG changes (i.e. diffuse ST elevation and PR depression with reciprocal changes in aVR)
- pleuritic chest pain: alleviated by sitting up and leaning forward
- pericardial friction rub: may be uni-, bi-, or triphasic; evanescent and rare
- ± fever, malaise

**Investigations**
- ECG: initially diffuse elevated ST segments ± depressed PR segment, the elevation in the ST segment is concave upwards → 2-5 d later ST isoelectric with T wave flattening and inversion
- CXR: normal heart size, pulmonary infiltrates
- Echo: performed to assess for pericardial effusion
- biomarkers: troponin I elevation may suggest myopericarditis

**Treatment**
- treat the underlying disease
- anti-inflammatory agents (i.e. high dose NSAIDs/ASA; steroid use controversial), analgesics
- physical activity restriction until symptom resolution

**Complications**
- recurrent episodes of pericarditis, atrial arrhythmia, pericardial effusion, tamponade, constrictive pericarditis
Pericardial Disease

Pericardial Effusion

Etiology
- transudative (serous)
- CHF, hypoalbuminemia/hypoproteinemia, hypothyroidism
- exudative (serosanguinous or bloody)
  - causes similar to the causes of acute pericarditis
  - may develop acute effusion secondary to hemopericardium (trauma, post-MI myocardial rupture, aortic dissection)
- physiologic consequences depend on type and volume of effusion, rate of effusion development, and underlying cardiac disease

Signs and Symptoms
- may be asymptomatic or similar to acute pericarditis
- dyspnea, cough
- extra-cardiac (esophageal/recurrent laryngeal nerve/tracheo-bronchial/phrenic nerve irritation)
- JVP increased with dominant "x" descent
- arterial pulse normal to decreased volume, decreased pulse pressure
- auscultation: distant heart sounds ± rub
- Ewart's sign

Investigations
- ECG: low voltage, flat T waves, electrical alternans (classic, but not a sensitive sign to exclude effusion)
  - be cautious in diagnosing STEMI in a patient with pericarditis and an effusion – antiplatelets may precipitate hemorrhagic effusion
- CXR: cardiomegaly, rounded cardiac contour
- ER: bedside ultrasound with subxiphoid view showing fluid in pericardial sac
- Echo (procedure of choice): fluid in pericardial sac
- pericardiocentesis: definitive method of determining transudate vs. exudate, identify infectious agents, neoplastic involvement

Treatment
- mild: frequent observation with serial echos, treat underlying cause, anti-inflammatory agents
- severe: treat as in tamponade (see Cardiac Tamponade)

Cardiac Tamponade

Etiology
- major complication of rapidly accumulating pericardial effusion
- cardiac tamponade is a clinical diagnosis
- any cause of pericarditis but especially trauma, malignancy, uremia, proximal aortic dissection with rupture

Pathophysiology
- high intra-pericardial pressure → decreased venous return → decreased diastolic ventricular filling → decreased CO → hypotension and venous congestion

Signs and Symptoms
- tachypnea, dyspnea, shock, muffled heart sounds
- pulsus paradoxus (inspiratory fall in systolic BP >10 mmHg during quiet breathing)
- JVP "x" descent only, blunted "y" descent
- hepatic congestion/peripheral edema

Investigations
- ECG: electrical alternans (pathognomonic variation in R wave amplitude), low voltage
- echo: pericardial effusion, compression of cardiac chambers (RA and RV) in diastole
- cardiac catheterization

Treatment
- pericardiocentesis: Echo-guided
- pericardiotomy
- avoid diuretics and vasodilators (these decrease venous return to already under-filled RV → decrease LV preload → decrease CO) as well as mechanical ventilation
- IV fluid may increase CO
- treat underlying cause

Constrictive Pericarditis

Etiology
- chronic pericarditis resulting in fibroed, thickened, adherent, and/or calcified pericardium
- any cause of acute pericarditis may result in chronic pericarditis
- major causes are idiopathic, post-infectious (viral, TB), radiation, post-cardiac surgery, uremia, MI, collagen vascular disease
Signs and Symptoms
- dyspnea, fatigue, palpitations
- abdominal pain
- may mimic CHF (especially right-sided HF)
  - ascites, hepatosplenomegaly, edema
- increased JVP, Kussmaul’s sign (paradoxical increase in JVP with inspiration), Friedreich’s sign (prominent “y” descent)
- BP usually normal (and usually no pulsus paradoxus)
- precordial examination: ± pericardial knock (early diastolic sound)
  - see Table 17 for differentiation from cardiac tamponade

Investigations
- ECG: non-specific – low voltage, flat T wave, ± AFib
- CXR: pericardial calcification, effusions
- echo/CT/MRI: pericardial thickening, ± characteristic echo-Doppler findings
- cardiac catheterization: equalization of end-diastolic chamber pressures (diagnostic)

Treatment
- medical: diuretics, salt restriction
- surgical: pericardiectomy (only if refractory to medical therapy)
- prognosis best with idiopathic or infectious cause and worst in post-radiation; death may result from heart failure

General Principles

Drug Nomenclature

- **chemical name**: describes chemical structure; consistent in all countries via International Union of Applied Chemistry (e.g. N-(4-hydroxyphenyl)acetamide is acetaminophen)
- **DIN or NDC**: DIN assigned by Health Canada; NDC assigned by FDA (US)
- **non-proprietary name**: approved name (post-phase III trial), official name (listed in pharmacopeia), or generic name (off-patent) such as acetaminophen
- **proprietary (trade) name**: the brand name or registered trademark (e.g. Tylenol®)

Phases of Clinical Drug Testing

- **pre-clinical**: testing a drug in a controlled environment (lab) on animal or human cells before human testing to discern the PK and toxicological profile
- **phase I**: first administration to healthy human volunteers, following animal studies; to determine PK and PD
- **phase II**: first administration to patients, small sample sizes; to determine initial safety and efficacy, dose range, PK, and PD
- **phase III**: double-blinded RCT; comparative (new drug vs. placebo or standard of care) to establish safety and efficacy
- **phase IV**: post-marketing surveillance, wide distribution; to determine effectiveness (in contrast to safety and efficacy) and monitor long-term drug effects, and previously unappreciated ADRs

Drug Administration

- choice of route of administration depends on: drug properties, local and systemic effects, desired time to onset and/or duration of action, and patient characteristics

Table 1. Routes of Drug Administration

<table>
<thead>
<tr>
<th>Route</th>
<th>Advantage</th>
<th>Potential Disadvantages</th>

Acronyms

- **ACE**: angiotensin converting enzyme
- **ACH**: acetylcholine
- **ADE**: adverse drug event
- **ADR**: adverse drug reaction
- **ARB**: angiotensin receptor blocker
- **AUC**: area under the concentration-time curve
- **BBB**: blood brain barrier
- **CI**: clearance
- **Cr**: creatinine
- **CSF**: cerebrospinal fluid
- **CSFa**: certain safety factor
- **CYP**: cytochrome P450 enzyme
- **DIN**: drug identification number
- **F**: bioavailability
- **FDA**: Food and Drug Administration
- **GFR**: glomerular filtration rate
- **HH**: Henderson-Hasselbalch
- **NDC**: National Drug Code
- **NE**: norepinephrine
- **NPO**: nothing by mouth
- **PD**: pharmacodynamics
- **PDE**: phosphodiesterase
- **P-gp**: P-glycoprotein
- **PK**: pharmacokinetics
- **RCT**: randomized controlled trial
- **TBW**: total body water
- **TDM**: therapeutic drug monitoring
- **TI**: therapeutic index
- **Vd**: volume of distribution

Common Latin Abbreviations

- **q**: each, every
- **OD/bid/tid/qid**: once/twice/three/four times a day
- **hs**: at bedtime
- **ac/pc/cc**: before/after/with meals
- **prn**: as necessary
- **gtt**: drops
- **ung**: ointment
- **ud**: as directed
- **od/os/ou**: right/left/each ear

NOTE: Certain abbreviations, symbols, and dose designations may contribute to medication errors. For more information, refer to guidelines by the Institute for Safe Medication Practices (ISMP)
Pharmacokinetics

- study of “what the body does to a drug” – i.e. the fate of a drug following administration
- definition: relationship between drug administration, time-course/rate of absorption and distribution, concentration changes in the body compartments, and the drug's removal from the body

Absorption

- definition: movement of the drug from the site of administration into plasma

Mechanisms of Drug Absorption

- most drugs are absorbed into the systemic circulation via passive diffusion
- other mechanisms include active transport, facilitated diffusion, and pinocytosis/phagocytosis

Factors Affecting the Rate and Extent of Drug Absorption

- $P_{ow}$: local blood flow at the site of administration (e.g. sublingual vessels facilitate rapid absorption of sublingually-administered medications)
- molecular size (e.g. drugs with smaller molecular weight are absorbed faster)
- pH and drug ionization
  - drugs are usually weak acids (e.g. ASA) or weak bases (e.g. ketoconazole) and thus exist in ionized and non-ionized forms
  - non-ionized forms cross cell membranes more readily than ionized (charged) forms
  - the ratio of ionized to non-ionized forms is determined by body compartment pH and drug pKa (H-H equation)
- total surface area for absorption
  - small intestinal villi are the primary site of absorption for most oral drugs

Bioavailability (F)

- definition: proportion of dose that reaches systemic circulation in an unchanged state
- lower F usually reflects limited drug absorption or first-pass effect
- IV dose has 100% bioavailability (F = 1)

First-Pass Effect

- definition: drug metabolism by the liver and/or the gut before it reaches systemic circulation, resulting in reduced F
- occurs with PO administration of a drug: GI tract (absorption) $\rightarrow$ portal vein to liver (first-pass metabolism) $\rightarrow$ systemic circulation
- 50% of the PR administered drug absorbed in colon bypasses the portal system. CYP3A4 in the enterocytes reduce the bioavailability of some rectally administered medications

Efflux Pump

- P-gp is a protein found in various parts of the body that acts as a multidrug efflux pump involved in the transport of drugs out of cells
- for example, P-gp opposes intestinal absorption (e.g. dabigatran etexilate) and also enhances renal elimination of certain drugs (e.g. digoxin, etoposide, paclitaxel, tacrolimus, cyclosporine)
- some drugs (e.g. macrolide antibiotics) inhibit P-gp function, leading to increased serum concentrations of drugs transported by P-gp; P-gp inducers (e.g. rifampin, St. John's wort) do the opposite
- some tumours overexpress P-gp leading to multidrug resistance to chemotherapeutic agents

Distribution

- definition: movement of drugs between different body compartments and to the site of action
- major body fluid compartments include plasma, interstitial fluid, intracellular fluid, transcellular fluid (e.g. CSF, peritoneal, pleural)
- tissue compartments include fat, brain

Factors Affecting the Rate and Extent of Drug Distribution

- physiochemical properties of the drug (e.g. $P_{ow}$ and pKa)
- pH of fluid
- plasma protein binding
- binding within compartments (i.e. depots)
- regional blood flow
Volume of Distribution
- Vd: the apparent volume of fluid into which a drug distributes
- maximum actual Vd (anatomic fluid volume accessible to drug) = TBW (~40 L for average adult)
  - a calculated value (Vd) = amount of drug in body ÷ plasma drug concentration
  - a theoretical value that does not correspond to an anatomical space (i.e. can exceed TBW)
  - small Vd corresponds to a drug that concentrates in plasma and/or binds plasma proteins to a high degree
  - large Vd corresponds to a drug that distributes into tissues (fat, muscle, etc.); most is not in blood (measured space); it therefore "appears" to distribute in a large volume
  - Vd of plasma protein bound drugs can be altered by liver and kidney disease
  - Vd of drugs change with age
    - in geriatric populations, there is a reduction in total body water and total muscle mass, but an increase in total body fat resulting in an increase in the Vd of lipophilic drugs
  - Vd of drugs will change in the geriatric population based on the drug P<sub>low</sub>
- example: amiodarone distributes into TBW (actual Vd ~40 L), but it concentrates in fat tissues yielding an apparent Vd of 400 L; therefore, to achieve a given plasma concentration of amiodarone, we dose as though the drug distributes into 400 L of body fluid

Plasma Protein Binding
- drug molecules in the blood exist in an equilibrium of two forms:
  1. bound to plasma protein: acidic drugs bind to albumin, basic drugs bind to α1-acid glycoprotein
  2. free or unbound: can leave the circulation to distribute into tissues and exert an effect, subject to metabolism and elimination
- bound fraction is determined by drug concentration, binding affinity, and plasma protein concentration (number of binding sites)
- reduced number of binding sites (e.g. hypoalbuminemia) or saturation of binding sites (e.g. competition/displacement) may result in increased concentration of free drug, which is often metabolized with no harmful effects, although toxicity is possible

Depots
- a body compartment in which drug molecules tend to be stored and released slowly over a long period of time
- fat is a depot for very lipid soluble drugs (e.g. diazepam)
- some oil-based medications are injected IM for slow release (e.g. depot medroxyprogesterone acetate q3mo; depot risperidone q2wk)

Barriers (relative)
- body structures that limit or prevent diffusion of drug molecules, such as the placenta or BBB (a barrier composed of tight junctions between capillary endothelial cells and astrocytes)
- many of these barriers result, in part, from the activity of multidrug efflux pumps (e.g. P-gp), which serve as a natural defense mechanism against drugs and xenobiotics
- need to consider dosing route if drugs are meant to cross these barriers
- barriers are important in determining site of action and side effects profile of drugs (e.g. CNS depression if drug crosses BBB, risk of harm to a fetus if drug crosses placental barrier)

Metabolism (Biotransformation)
- definition: chemical transformation of a drug in vivo
- sites of biotransformation include liver (main), GI tract, lung, plasma, kidney
- as a result of the process of biotransformation:
  - an inactive prodrug may be activated (e.g. tamoxifen to endoxifen; codeine to morphine)
  - a drug may be changed to another active metabolite (e.g. diazepam to oxazepam and others)
  - a drug may be changed to a toxic metabolite (e.g. meperidine to normeperidine)
  - a drug may be inactivated (most drugs)

Drug Metabolizing Pathways
- phase I (P<sub>450</sub>) reactions
  - minor molecular changes introduce or unmask polar groups on a parent compound to increase water solubility (e.g. oxidation-reduction, hydrolysis, hydroxylation, demethylation); the change in P<sub>low</sub> is typically minimal compared to phase II, and often phase I places a polar 'handle' on a lipophilic drug to allow for phase II
  - mediated by CYPs found in the endoplasmic reticulum (primarily in hepatocytes)
  - product of the reaction can be excreted or undergo further phase II reactions
- phase II (conjugation) reactions
  - conjugation with large polar endogenous substrates (e.g. glucuronidation, glutathione conjugation, sulfation)
  - dramatically increases water solubility and renal elimination
  - can result in biologically active metabolites (e.g. glucuronides of morphine)
  - can occur independently of phase I reactions
Factors Affecting Drug Biotransformation

- **genetic polymorphisms** of metabolizing enzymes
  - for some enzymes, individual genotypes may alter the rate of drug metabolism (e.g. poor, intermediate, extensive, or ultrarapid metabolizers)
  - may lead to toxicity or ineffectiveness of a drug at a normal dose
- tamoxifen and codeine are prodrugs activated by CYP2D6 (nonfunctional alleles reduce effectiveness, whereas duplicated alleles impart "ultra-rapid metabolizer" phenotype)
- warfarin is metabolized by CYP2C9 (nonfunctional alleles lead to greater effect and lower dose requirements)

- **enzyme inhibition** may sometimes be due to other drugs
  - CYP inhibition leads to an increased concentration and bioavailability of the substrate drug (e.g. erythromycin [CYP3A4 inhibitor] can predispose patients to simvastatin toxicity [metabolized by CYP3A4])
  - grapefruit juice is a potent inhibitor of intestinal CYP3A4, resulting in numerous drug interactions (e.g. saquinavir AUC increased 3-fold, simvastatin 17-fold)

- **enzyme induction** may sometimes be due to other drugs
  - CYP induction leads to an increased concentration and bioavailability of the substrate drug (e.g. phenobarbital can induce the metabolism of OCPs) by inducing the CYP system
  - certain medications enhance gene transcription leading to an increase in the activity of a metabolizing enzyme
  - a drug may induce its own metabolism (e.g. carbamazepine) or that of other drugs (e.g. CYP inhibition leads to an increased concentration and bioavailability of the substrate drug)

- **liver dysfunction** (e.g. hepatitis, alcoholic liver, biliary cirrhosis, or hepatocellular carcinoma) may decrease drug metabolism but this may not be clinically significant due to the liver's reserve capacity

- **renal disease** often results in decreased drug clearance

- **extremes of age** (neonates or elderly) have reduced biotransformation capacity, and doses should be adjusted accordingly

- **nutrition**: insufficient protein and fatty acid intake decreases CYP biotransformation, and vitamin/mineral deficiencies may also impact other metabolizing enzymes

- **alcohol**: while acute alcohol ingestion inhibits CYP2E1, chronic consumption can induce CYP2E1 and increase risk of hepatocellular damage from acetaminophen by increasing the production of acetaminophen's toxic metabolite (NAPQI)

- **smoking** can induce CYP1A2, thus increasing the metabolism of some drugs (e.g. theophylline, antipsychotics)

## Eliminatios

- **definition**: removal of drug from the body

### Routes of Drug Elimination

- **kidney** (main organ of elimination)
  - renal drug clearance = (glomerular filtration + tubular secretion) – (tubular reabsorption)
  - two mechanisms:
    1. **glomerular filtration**
       - a passive process, so that only the free drug fraction can be eliminated
       - drug filtration rate depends on GFR, degree of protein binding of drug, and size of drug
    2. **tubular secretion**
       - an active process that is saturatable allowing both protein-bound and free drug fractions to be excreted
       - distinct transport mechanisms for weak acids (e.g. penicillin, salicylic acid, probenecid, chlorothiazide) and weak bases (e.g. quinine, quaternary ammonium compounds such as choline)
       - drugs may competitively block mutual secretion if both use the same secretion system (e.g. probenecid can reduce the excretion of penicillin)

- **tubular reabsorption**: drugs can be actively or passively reabsorbed back to the systemic circulation, countering elimination mechanisms

- **renal function** (assessed using serum Cr levels) decreases with age (7.5 mL/min per decade) and is affected by many disease states such as diabetes

- **stool**: some drugs and metabolites are actively excreted in the bile or directly into the GI tract
  - enterohepatic reabsorption counteracts stool elimination, and can prolong the drug's duration in the body
  - some glucuronic acid conjugates that are excreted in bile may be hydrolyzed in the intestines by bacteria back to their original form and can be systemically reabsorbed

- **lungs**: elimination of anesthetic gases and vapours by exhalation

- **saliva**: saliva concentrations of some drugs parallel their plasma concentrations (e.g. rifampin)
Pharmacokinetics

**Pharmacokinetic Calculation**

- **definition**: the quantitative description of the various steps of drug disposition (i.e. how drugs move through the body)
- the pharmacokinetic principles of ADME (absorption, distribution, metabolism, and elimination) can be graphically represented on a graph of concentration vs. time

**Time Course of Drug Action**

- many kinetic parameters are measured using IV dosing, such that absorption is immediate and distribution for most drugs is rapid; thus elimination is the main process being measured
- the concentration axis is converted to a log10 concentration to allow for easier mathematical calculations
- drugs such as warfarin can exhibit hysteresis (for a single drug concentration, there may be two different response levels)

**Half-Life**

- **definition**: time taken for the serum drug level to fall 50% during elimination
- drugs with first order kinetics require five half-lives to reach steady state with repeated dosing or for complete drug elimination once dosing is stopped

**Steady State**

- drug concentration remains constant when amount of drug entering the system is the same as the amount eliminated from the system
- drug levels in therapeutic drug monitoring are of greatest utility when the steady state has been reached
- special situations
  - use a loading dose for drugs with a long half-life and when there is clinical need to rapidly achieve therapeutic levels (e.g. amiodarone, digoxin, phenytoin)
  - use continuous infusion for drugs with a very short half-life and when there is need for a long-term effect and multiple or frequently repeated doses are too inconvenient (e.g. nitroprusside, unfractionated heparin, naloxone)

**Clearance**

- a quantitative measurement of the body fluid volume from which a substance is removed per unit time
- CI = rate of elimination of drug ÷ plasma drug concentration
- must consider CI from a specific part of the body and total body CI

**Elimination Kinetics**

- first-order kinetics (most common type)
  - constant fraction of drug eliminated per unit time
  - some drugs can follow first-order kinetics until elimination is saturated (usually at large doses) at which point the CI is less than would be predicted for a given concentration
  - shows linear relationship when plotted on a graph of concentration (log) vs. time (linear)
- zero-order kinetics (less common, associated with overdose, e.g. alcohol)
  - constant amount of drug eliminated per unit time, regardless of concentration; concept of half-life does not apply
  - the concentration axis is converted to a log (concentration) to allow for easier mathematical calculations
- non-linear kinetics (much less common)
  - unlike first-order kinetics which assumes no change in PK parameter with drug dose, non-linear kinetics is considered dose-dependent
  - saturation of various ADME processes creates non-linear kinetics
  - the complexity of dosing drugs with non-linear kinetics has resulted in creation of drug-specific nomograms to aid clinicians in dosing, with these drugs often being the target of therapeutic drug monitoring
  - examples: phenytoin, theophylline

**Loading and Maintenance Doses**

- loading doses are used when immediate effect is needed with parenteral administration being the most common way of giving a large dose to "fill up" the volume of distribution
- maintenance doses are given after a loading dose OR drug regimen can begin with maintenance doses
  - steady state levels are achieved after ~5 half lives
  - can be given as either a continuous infusion (rare) or more commonly as intermittent oral doses
Pharmacodynamics

- study of “what the drug does to the body”

**Dose-Response Relationship**

- graded dose-response relationships: relates dose to intensity of effect

**Efficacy**

- the maximum biological response produced by a drug
- measured by $E_{max}$ (the maximal response that a drug can elicit in a RCT or under optimal circumstances)

**Potency**

- measured by $EC_{50}$ (the concentration of a drug needed to produce 50% of $E_{max}$)
- a drug that reaches its $EC_{50}$ at a lower dose is more potent

![Log(dose)-response curve illustrating efficacy and potency](image1)

**Effects of Drugs on Receptors**

**Agonists**

- drugs that mimic the effects of the endogenous ligand and evoke a response when bound to the receptor
  - **affinity**: the ability of the agonist to bind to the receptor (e.g. the β2-agonist salbutamol has greater affinity for β2-receptors than β1-receptors)
  - **efficacy**: the ability to recapitulate endogenous response via the receptor interaction (e.g. binding of salbutamol to β2-receptors results in smooth muscle relaxation)
- drug efficacy in an RCT is different than efficacy in the context of pharmacological principles
- **full agonists**: can elicit a maximal effect at a receptor (e.g. methadone and morphine on the µ opioid receptor system)
- **partial agonists**: can only elicit a partial effect, no matter the concentration at the receptor (i.e. reduced efficacy compared to full agonists) (e.g. buprenorphine on the µ opioid receptor system)

**Antagonists**

- drugs that reduce the action of an agonist or of an endogenous ligand
- **chemical antagonism**: direct chemical interaction between agonist and antagonist prevents agonist-receptor binding (e.g. chelating agents for removal of heavy metals)
- **physiological/functional antagonism**: two agonists that act independently at different receptors and have opposite physiological effects (e.g. acetylcholine at the muscarinic receptor compared to epinephrine at the adrenergic receptor)
- **pharmacological antagonism**: antagonist inhibits agonist through acting on receptor or alternative effector site
- **reversible and irreversible competitive antagonism**
  - drugs that exert no direct effect upon binding to a given receptor (i.e. zero efficacy)
  - reversible competitive antagonists reversibly bind to the same receptor as the agonist, thus displacing it (e.g. naloxone is an antagonist to morphine or heroin)
  - irreversible antagonists form a covalent bond with the receptor, thus irreversibly blocking substrates from binding (e.g. phenoxybenzamine forms a covalent bond with adrenergic receptors preventing adrenaline and NE from binding)
- **non-competitive antagonism**
  - antagonist binds to an alternate site near the agonist site, producing allosteric effects that change the ability of the agonist to bind (e.g. organophosphates irreversibly bind acetylcholinesterase)

![Log(dose)-response curve for competitive reversible antagonism](image2)

![Log(dose)-response curve for irreversible antagonism](image3)
Effectiveness and Safety

Effectiveness
- ED50 (effective dose): the dose of a drug needed to cause a therapeutic effect in 50% of a test population of subjects

Safety
- LD50 (lethal dose): the dose of a drug needed to cause death in 50% of a test population of subjects
- TD50 (toxic dose): the dose needed to cause a harmful effect in 50% of a test population of subjects

Therapeutic Indices

Therapeutic Index: TD50/ED50
- reflects the "margin of safety" for a drug – the likelihood of a therapeutic dose to cause serious toxicity or death
- the larger the TI, the safer a drug
- common drugs with a narrow TI that require therapeutic drug monitoring include: digoxin, theophylline, warfarin, lithium, and cyclosporine
- factors that can change the TI
  - presence of interacting drugs
  - changes in drug ADME

Certain Safety Factor: TD1/ED99
- >1 translates to a dose effective in at least 99% of the population and toxic in less than 1% of the population
Therapeutic Drug Monitoring

• **definition**: using serum drug concentration data to optimize drug therapy (e.g. dose adjustment, monitor compliance) serum drug samples are usually taken when the drug has reached steady state (after approximately 5 half-lives)

• TDM is often used for drugs that have: narrow TIs, unpredictable dose-response relationships, significant consequences associated with therapeutic failure or toxicity, and wide inter-patient PK variability

• nomograms are often used for narrow TI drugs, particularly in the setting of patients with complex clinical factors such as renal insufficiency, hepatic failure, dialysis, hypoalbuminemia

• examples of drugs that require therapeutic drug monitoring include:
  - vancomycin
  - aminoglycosides (gentamicin, tobramycin)
  - digoxin
  - phenytoin and other anticonvulsants
  - warfarin
  - lithium

Adverse Drug Reactions

• adverse drug events (ADEs) are events that occur while a patient is on a drug at either appropriate or inappropriate doses. A causal relationship is not required

• adverse drug reactions (ADRs) are reactions to drugs that occur when a drug is used for the appropriate indication at normal therapeutic doses

<table>
<thead>
<tr>
<th>Classification</th>
<th>Definition</th>
<th>Characteristics</th>
</tr>
</thead>
<tbody>
<tr>
<td>A (Augmented)</td>

<td>Withdrawal</td>
<td>Occurs after cessation of drug use (e.g. opiate withdrawal)</td>
</tr>
</tbody>
</table>

Tips to Reduce Drug-Related Adverse Events in the Elderly

• Be mindful of longstanding medications that have never been adjusted for patient age or renal or hepatic function

• Consider whether medications initiated during hospital admission are needed long-term (and whether the discharge dose is appropriate for maintenance)

• Avoid polypharmacy by decreasing the dose of or discontinuing medications that are causing side effects

• Verify adherence to medications before automatically increasing the dose of subtherapeutic treatment

• When prescribing medications, use those with a wide therapeutic window

• Review the patient’s problem list and reconcile current medications to avoid duplication or inappropriate dosing/frequency
**Approach to Suspected Adverse Drug Reactions**

- history and physical exam: signs and symptoms of reaction (e.g. rash, fever, hepatitis, anaphylaxis), timing, risk factors, detailed medication history including all drugs and timing, de-challenge (response when drug is removed), and re-challenge (response when drug is given again, if applicable)
- differentiate between drug therapy vs. disease pathophysiology
- treatment: stop the drug, supportive care, symptomatic relief. Specific interventions (e.g. steroids, immunosuppressants) used for some ADRs
- resources: check recent literature, Health Canada, and FDA; contact the pharmaceutical company; call Poison Control (1-888-268-9017) if overdose or poisoning suspected; check with MotherToBaby (https://mothertobaby.org/) in cases involving pregnant or breastfeeding women
- report all suspected ADRs that are: 1) unexpected, 2) serious, or 3) reactions to recently marketed drugs (on the market <5 yr) regardless of nature or severity
  - Canadian Adverse Drug Reaction Monitoring Program available for online reporting

**Variability in Drug Response**

- recommended patient dosing is based on clinical research and represents mean values for a select population, but each person may be unique in their dosing requirements
- possible causes of individual variability in drug response include problems with:
  - intake: patient adherence
  - PK
  - absorption: vomiting, diarrhea, or steatorrhea; first pass effect increased due to enzyme induction or decreased due to liver disease
  - drug interactions (e.g. calcium carbonate complexes with iron, thyroxine, and fluoroquinolones)
  - distribution: very high or low percentage body fat; intact or disrupted BBB; patient is elderly or a neonate, or has liver dysfunction
  - biotransformation and elimination: certain genetic polymorphisms or enzyme deficiencies related to drug metabolism (e.g. acetylcysteinesterase deficiency, CYP polymorphism); kidney or liver dysfunction
  - PD: genetic variability in drug response (e.g. immune-mediated reactions); diseases that affect drug PD; drug tolerance or cross-tolerance

**Drug Interactions**

- concomitant prescriptions: one drug alters the effect of another by changing its PK and/or PD
- PK interactions involve changes in drug concentration
  - absorption: alterations in gastrointestinal pH, gastric emptying, intestinal motility, gut transporters
  - metabolism: alterations in drug metabolizing enzymes (e.g. CYP)
  - excretion: alterations in renal elimination
- PD interactions are due to two drugs that exert similar effects (additive) or opposing effects (subtractive)
- drug interactions can also involve herbal medications (e.g. St. John's wort) and food (e.g. grapefruit juice)

**Autonomic Pharmacology**

**Peripheral Nervous System**

- Somatic
  - Sympathetic (SNS) Fight or Flight
  - Parasympathetic (PNS) Rest and Digest
- Autonomic (ANS)

**Figure 7. Subdivisions of the peripheral nervous system**

- most organs are innervated by both sympathetic and parasympathetic nerves, which have opposing effects (see Neurology, N8)
- ACh and NE are the main neurotransmitters of the autonomic NS
- ACh binds to cholinergic receptors, which include nicotinic and muscarinic receptors
- NE binds to adrenergic receptors, which principally include β1, β2, α1, and α2
- ACh action is terminated by metabolism in the synaptic cleft by acetylcholinesterase and in the plasma by pseudocholinesterase

**Examples of Clinically Relevant Drug Interactions**

**Antibiotic Allergies - What is the Risk of Cross-Reactivity?**

- In clinical practice, cross-reactivity between drugs presents a problem for both patients and physicians
- In the case of penicillin allergy, cross-reactivity to cephalosporins is less than 2%, however, in patients who have a history of true anaphylactic reaction, cross-reactivity is closer to 40%
- Conversely, cross-reactivity between penicillins and carbapenems is <1%
- The term “sulfa allergy” is often misused and has no formal definition. Current evidence suggests cross-reactivity between sulfonamide antibiotics (e.g. sulfamethoxazole-trimethoprim) and non-antibiotic sulfonamides, including loop diuretics (e.g. furosemide), thiazide diuretics (e.g. hydrochlorothiazide), protease inhibitors containing an arylamine group (e.g. darunavir), carbonic anhydrase inhibitors (e.g. acetazolamide), and sulfonyleureas (e.g. glipizide)
• acetylcholinesterase inhibitors (pyridostigmine, donepezil, galantamine, rivastigmine) can be used to increase ACh levels in conditions such as myasthenia gravis or Alzheimer’s disease
• NE action is terminated by reuptake at the presynaptic membrane, diffusion from the synaptic cleft, and degradation at monoamine oxidase (MAO) and catechol-O-methyl transferase (COMT)

Parasympathetic Nervous System

• blood vessels, adrenals, sweat glands, spleen capsule, and adrenal medulla do NOT have parasympathetic innervation
• parasympathetic pre-ganglionic fibres originate in the lower brainstem from cranial nerves III, VII, IX, X, and in the sacral spinal cord at levels S2-S4 and connect with post-ganglionic fibres via nicotinic receptors in ganglionic cells located near or within the target organ
• post-ganglionic fibres connect with effector tissues via:
  M1 muscarinic receptors located in the CNS
  M2 muscarinic receptors located in smooth muscle, cardiac muscle, and glandular epithelium

Sympathetic Nervous System

• sympathetic pre-ganglionic fibres originate in the spinal cord at spinal levels T1-L2/L3
• pre-ganglionic fibres connect with post-ganglionic fibres via nicotinic receptors located in one of two groups of ganglia:
  1. paravertebral ganglia (i.e. the sympathetic trunk) that lie in a chain close to the vertebral column
  2. pre-vertebral ganglia (i.e. celiac and mesenteric ganglia) that lie within the abdomen
• post-ganglionic fibres connect with effector tissues via:
  M1 receptors in cardiac tissue
  M2 receptors in smooth muscle of bronchi and GI tract
  a1 receptors in vascular smooth muscle
  a2 receptors in vascular smooth muscle
  M3 muscarinic receptors located in sweat glands

Opioid Therapy and Chronic Non-Cancer Pain

General Management Principles

• when first considering therapy for patients with chronic non-cancer pain, optimize non-opioid pharmacotherapy and non-pharmacologic therapy, rather than a trial of opioids (strong recommendation)
• general approaches to opioid use should include avoiding initial high doses when possible and a slow, collaborative approach when tapering
• for patients with chronic non-cancer pain beginning opioid therapy, restrict the prescribed dose to less than 90 mg morphine equivalents daily (MED), and ideally less than 50 MED, rather than having no upper limit or a higher limit on dosing
• for patients with chronic non-cancer pain who are currently using 90 mg morphine equivalents of opioids per day or more, encourage slow, collaborative taper opioids to the lowest effective dose, potentially including discontinuation, rather than making no change in opioid therapy
• for patients with chronic non-cancer pain who are using opioids and experiencing serious challenges in tapering, formal multidisciplinary program is suggested
• for more information, please refer to national opioid guidelines for a comprehensive approach to opioid use (link http://nationalpaincentre.mcmaster.ca/guidelines.html)

Skin Anatomy

- **skin**
  - divided anatomically into epidermis, dermis, and subcutaneous tissue

- **epidermis**
  - avascular: receives its nutrition from the dermal capillaries
  - derived from keratinocytes with the youngest presenting at the stratum basale
  - cells progress from stratum basale to stratum corneum in about 4 wk
  - stratum basale (germinativum): mitotic figures that give rise to keratinocytes
  - stratum spinosum (prickle cells): junctions in this layer (tonofilaments) give the epidermis its strength
  - stratum granulosum: flat cells containing basophilic granules
  - stratum lucidum: transparent layers of packed dead cells
  - stratum corneum: flat scales of the water-resistant protein keratin

- **cells of the epidermis**
  - keratinocytes: located in all layers of the epidermis except the stratum corneum; connected to each other by desmosomes
  - melanocytes: located in the stratum basale; keratinocyte to melanocyte ratio in the basal layer is 10:1; melanocyte number is equal among races; produce melanosomes containing melanin, which are transferred to keratinocytes
  - Langerhans cells: dendritic cells which are important for immune surveillance
  - Merkel cells: dendritic cells which are important for immune surveillance

- **dermis**
  - comprises of connective tissue divided into two regions
  - papillary: contains numerous capillaries that supply nutrients to the dermis and epidermis
  - reticular: provides a strong structure for skin; consists of collagen bundles woven together along with elastic fibres, fibroblasts, and macrophages

- **cells of dermis**
  - fibroblasts: produce collagen, elastin, and ground substance
  - mast cells: release histamines which mediate type I hypersensitivity
  - other components of dermis include: blood vessels, nerves, pilosebaceous units, and sweat glands

- **subcutaneous tissue** (hypodermis)
  - consists primarily of adipose cells, larger calibre vessels, nerves, and fascia
Epidermal Appendages
- epidermal in origin, can extend into the dermis; includes hair, nails, and cutaneous glands
- pilosebaceous unit = hair + hair follicle + sebaceous gland + arrector pili muscle

Cutaneous Glands
- sebaceous gland: part of pilosebaceous unit; produces sebum which is secreted into the hair follicle via the sebaceous duct, where it covers the skin surface (protective function)
  - sebaceous glands cover entire skin surface and are absent only in non-hair bearing areas (e.g. palms, soles, lips)
- apocrine sweat gland: apocrine duct empties into hair follicle above sebaceous gland
  - found in axillae and perineum
  - likely a vestigial structure, functions in other species to produce scent (e.g. pheromones)
- eccrine sweat gland: not part of pilosebaceous unit
  - found over entire skin surface except lips, nail beds, and glans penis
  - important in temperature regulation via secretion of sweat to cool skin surface

Skin Function
- protection
  - due to continuous recycling and avascularity of epidermis
  - barrier to UV radiation (melanin), mechanical/chemical insults (sensory/mechanoreceptors), pathogens (immune cells), and dehydration (lipid rich barrier)
- thermal regulation
  - insulation to maintain body temperature in cool environments via peripheral vasoconstriction, hair, and subcutaneous adipose tissue
  - dissipation of heat in warm environments via increased activity of sweat glands and increased blood flow within dermal vascular networks
- sensation
  - touch, pain, and temperature sensation
- metabolic function
  - vitamin D synthesis
  - energy storage (mainly in the form of triglycerides)

Morphology

Primary Lesions
Definition
- a de-novo initial lesion that has not been altered by trauma or manipulation, and has not regressed

<table>
<thead>
<tr>
<th>Profile</th>
<th>&lt;1 cm Diameter</th>
<th>≥1 cm Diameter</th>

</tr>
</tbody>
</table>

Secondary Lesions
Definition
- develop during the evolutionary process of skin disease, or created by manipulation, or due to complication of primary lesion (e.g. rubbing, scratching, infection)
- crust: dried fluid (serum, blood, or purulent exudate) originating from a lesion (e.g. impetigo)
- scale: excess keratin (e.g. seborrheic dermatitis)
- lichenification: thickening of the skin and accentuation of normal skin markings (e.g. chronic atopic dermatitis)
- fissure: a linear slit-like cleavage of the skin
- excoriation: a scratch mark
- erosion: a disruption of the skin involving the epidermis alone; heals without scarring
- ulcer: a disruption of the skin that extends into the dermis or deeper; may heal with scarring
- xerosis: pathologic dryness of skin (xeroderma), conjunctiva (xerophthalmia), or mucous membranes (xerostomia)
- atrophy: histological decrease in size or number of cells or tissues, resulting in thinning or depression of the skin
**Other Morphological Terms**

- **cyst**: an internally epithelial-lined structure containing semi-solid material or fluid
- **pustule**: an elevated lesion containing a collection of neutrophils (infectious or inflammatory in nature)
- **scar**: replacement fibrosis of dermis and subcutaneous tissue (hypertrophic or atrophic)
- **wheal**: a special form of papule or plaque that is transient (<24 h) and blanchable, often with a halo and central clearing, formed by edema in the dermis (e.g. urticaria)
- **comedone**: a special collection of sebum and keratin
  - open comedo (blackhead)
  - closed comedo (whitehead)
- **petechiae**: pinpoint extravasation of blood into dermis resulting in hemorrhagic lesions; non-blanchable, <3 mm in size
- **purpura**: larger than petechia, 3 mm-1 cm in size
- **ecchymosis**: larger than purpura, >1 cm in size (i.e. a “bruise”)
- **telangiectasia**: dilated superficial blood vessels; blanchable, reticulated, and of small calibre, can be associated with benign or malignant entities

**Patterns and Distribution**

- **acral**: relating to the hands and feet (e.g. perniosis, secondary syphilis)
- **annular**: ring-shaped (e.g. granuloma annulare)
- **folicular**: involving hair follicles (e.g. folliculitis)
- **guttate**: lesions following a “drop-like” pattern (e.g. guttate psoriasis)
- **Koebner phenomenon**: i.e. isomorphic response, appearance of lesions at an injury site (e.g. lichen planus, psoriasis, vitiligo)
- **morbilliform**: literally means “measles-like”, an eruption composed of macules and papules with truncal predominance
- **reticular**: lesions following a net-like pattern (e.g. livedo reticularis)
- **satellite**: small lesions scattered around the periphery of a larger lesion (e.g. candida diaper dermatitis)
- **serpiginous**: lesions following a snake-like pattern (e.g. cutaneous larva migrans)
- **target/targetoid**: concentric ring lesions, like a dartboard (e.g. EM)
- **other descriptive terms**: discrete, clustered, linear, confluent, dermatitic, indurated (i.e. hard or firm)

<td>May be post-traumatic, rarely syndromic</td>
<td>Most common cutaneous cyst in youth – middle age</td>
<td>Central punctum may rupture (foul, cheesy odour, creamy colour) and produce inflammatory reaction Can increase in size and number over time</td>
</tr>
<tr>
<td>Pilar Cyst (Trichilemmal)</td>
<td>Thick-walled cyst lined with stratified squamous epithelium and filled with dense keratin</td>
<td>Idiopathic Post-trauma</td>
<td>2nd most common cutaneous cyst F-M, hereditary</td>
<td>Rupture causes pain and inflammation</td>
</tr>
<tr>
<td>Dermoid Cyst</td>
<td>Rare, congenital hamartomas, which arise from inclusion of epidermis along embryonal cleft closure lines, creating a thick-walled cyst filled with dense keratin</td>
<td></td>
<td>Rare</td>
<td>If nasal midline, risk of extension into CNS</td>
</tr>
<tr>
<td>Ganglion Cyst</td>
<td>Cystic lesion that originates from joint or tendon sheath, called a digital mucous cyst when found on fingertip</td>
<td>Associated with osteoarthritis</td>
<td>Older age</td>
<td>Stable</td>
</tr>
<tr>
<td>Milium</td>
<td>Small epidermoid cyst, primarily arising from pluripotential cells in epidermal or adnexal epithelium Can be secondary to blistering, ulceration, trauma, topical corticosteroid atrophy, or cosmetic procedures</td>
<td>Any age 40-50% of infants</td>
<td>In newborns, spontaneously resolves in first 4 wk of life</td>
<td>No treatment Incision and expression of contents Electrodesiccation Topical retinoid therapy</td>
</tr>
</tbody>
</table>
**Fibrous Lesions**

**DERMATOFIBROMA**

**Clinical Feature**
- button-like, firm dermal papule or nodule, skin-coloured to red-brown
- majority are asymptomatic but may be pruritic and/or tender
- site: legs > arms > trunk
- dimple sign (Fitzpatrick's sign): lateral compression causes dimpling of the lesion

**Pathophysiology**
- benign tumour due to fibroblast proliferation in the dermis

**Etiology**
- unknown; may be associated with history of minor trauma (e.g. shaving or insect bites)
- eruptive dermatofibroma can be associated with SLE

**Epidemiology**
- adults, F>M

**Differential Diagnosis**
- dermatofibrosarcoma protuberans, malignant melanoma, Kaposi's sarcoma, blue nevus

**Investigations**
- biopsy if diagnosis is uncertain

**Management**
- no treatment required
- excision if bothersome

**SKIN TAGS**

**Clinical Feature**
- small (1-10 mm), soft, skin-coloured or darker pedunculated papule, often polypoid
- sites: eyelids, neck, axillae, inframammary, and groin

**Pathophysiology**
- benign outgrowth of skin

**Epidemiology**
- middle-aged and elderly, F>M, obese, can increase in size and number during pregnancy

**Differential Diagnosis**
- pedunculated seborrheic keratosis, compound or dermal melanocytic nevus, neurofibroma, fibroepithelioma of Pinkus (rare variant of BCC), nevus lipomatosis superficialis

**Management**
- excision, electrodessication, cryosurgery

**Hyperkeratotic Lesions**

**SEBORRHEIC KERATOSIS**

**Clinical Feature**
- known as ‘wisdom spots,’ ‘age spots,’ or ‘barnacles of life’
- well-demarcated waxy papule/plaque with classic ”stuck on” appearance
- rarely pruritic
- over time lesions appear more warty, greasy and pigmented
- sites: face, trunk, upper extremities (may occur at any site except palms or soles)

**Pathophysiology**
- very common benign epithelial tumour due to proliferation of keratinocytes and melanocytes

**Epidemiology**
- unusual <30 yr old
- M>F
- autosomal dominant inheritance
- Leser-Trelat: sudden appearance of SK that can be associated with malignancy, commonly gastric adenocarcinomas
**Differential Diagnosis**
- malignant melanoma (lentigo maligna, nodular melanoma), melanocytic nevi, pigmented BCC, solar lentigo, spreading pigmented AK

**Investigations**
- biopsy only if diagnosis uncertain

**Management**
- none required, for cosmetic purposes only
- cryotherapy, electrodessication, excision

**ACTINIC KERATOSIS (SOLAR KERATOSIS)**
- see Pre-Malignant Skin Conditions, D33

**KERATOACANTHOMA**
- see Malignant Skin Tumours, D34

**CORNS (HELOMATA)**

**Clinical Feature**
- firm papule with a central, translucent, cone-shaped, hard keratin core
- painful with direct pressure
- sites: most commonly on dorsolateral fifth toe and dorsal aspects of other toes

**Pathophysiology**
- localized hyperkeratosis induced by pressure on hands and feet

**Epidemiology**
- F>M, can be caused by chronic microtrauma

**Differential Diagnosis**
- calluses, plantar warts

**Management**
- relieve pressure with padding or alternate footwear, orthotics
- paring, topical salicylic acid

**Keloids**

**Clinical Feature**
- firm, shiny, skin-coloured or red-bluish papules/nodules that most often arise from cutaneous injury (e.g. piercing, surgical scar, acne), but may appear spontaneously
- extends beyond the margins of the original injury, and may continue to expand in size for yr with claw-like extensions
- can be pruritic and painful
- sites: earlobes, shoulders, sternum, scapular area, angle of mandible

**Pathophysiology**
- excessive deposition of randomly organized collagen fibres following trauma to skin

**Epidemiology**
- most common in black patients, followed by those of Asian descent (predilection for darker skin)
- M=F, all age groups

**Management**
- intrallesional corticosteroid injections
- silicone compression

**Corns vs. Warts vs. Calluses**
- Corns have a whitish yellow central translucent keratinous core; painful with direct pressure; interruption of dermatoglyphics
- Warts bleed with paring and have a black speckled central appearance due to thrombosed capillaries; plantar warts destroy dermatoglyphics (epidermal ridges)
- Calluses have layers of yellowish keratin revealed with paring; there are no thrombosed capillaries or interruption of epidermal ridges

**Keloids vs. Hypertrophic Scars**
- Keloids: extend beyond margins of original injury with claw-like extensions
- Hypertrophic scars: confined to original margins of injury
Pigmented Lesions

CONGENITAL NEVOMELANOCYTIC NEVI (CNMN)

Clinical Feature
- sharply demarcated pigmented papule or plaque with regular borders ± coarse hairs
- classified by size: small (<1.5 cm), medium (M1: 1.5-10 cm, M2: >10-20 cm), large (L1: >20-30 cm, L2 >30-40 cm), giant (G1: >40-60 cm, G2: >60 cm)
- may be surrounded by smaller satellite nevi

Pathophysiology
- nevomelanocytes in epidermis (clusters) and dermis (strands)

Epidemiology
- present at birth or develops in early infancy to childhood
- malignant transformation is rare (1-5%) and more correlated with size of the lesion
- neurocutaneous melanosis can occur in giant CNMN (melanocytes in the CNS)

Management
- take a baseline photo and observe lesion for change in shape, colour, or size out of proportion of growth
- surgical excision if suspicious, due to increased risk of melanoma
- MRI if suspicious for neurological involvement

OTHER CONGENITAL PIGMENTED LESIONS

Table 4. Comparison of Other Congenital Pigmented Lesions

<table>
<thead>
<tr>
<th>Clinical Feature</th>
<th>Pathophysiology</th>
<th>Epidemiology</th>
<th>Differential Diagnosis</th>
<th>Clinical Course and Management</th>
</tr>
</thead>
<tbody>
<tr>
<td>Café-au-lait Macule</td>
<td>Flat light brown lesions with smooth or jagged borders</td>
<td>Areas of increased melanogenesis</td>
<td>6 or more is suggestive of neurofibromatosis type I Also associated with McCune-Albright syndrome</td>
<td>Flat congenital melanocytic nevus, speckled lentiginous nevus</td>
</tr>
<tr>
<td>Speckled Lentiginous Nevus (nevus spilus)</td>
<td>Brown pigmented macular background (café-au-lait macule-like) with dark macular or papular speckles</td>
<td>Increased melanocyte concentration</td>
<td>Risk of melanoma similar to that of a CNMN of the same size</td>
<td>Café-au-lait macule, agminated lentigines, Becker's nevus</td>
</tr>
<tr>
<td>Dermal Melanocytosis (historically known as Mongolian Spot)</td>
<td>Congenital grey-blue solitary or grouped macules commonly on lumbosacral area</td>
<td>Ectopic melanocytes in dermis</td>
<td>99% occurs in Asian and Indigenous infants</td>
<td>Ecchymosis</td>
</tr>
</tbody>
</table>

ACQUIRED NEVOMELANOCYTIC NEVI

Clinical Feature
- common mole: well circumscribed, round, uniformly pigmented macules/papules <1.5 cm
- average number of moles per person: 18-40
- 3 stages of evolution: junctional NMN, compound NMN, and dermal NMN

Table 5. Evolution of Acquired Nevomelanocytic Nevi

<table>
<thead>
<tr>
<th>Type</th>
<th>Age of Onset</th>
<th>Clinical Feature</th>
<th>Histology</th>
</tr>
</thead>
<tbody>
<tr>
<td>Junctional</td>
<td>Childhood</td>
<td>Flat, regularly bordered, uniformly tan-dark brown, sharply demarcated macule</td>
<td>Melanocytes at dermal-epidermal junction above basement membrane</td>
</tr>
<tr>
<td>Compound</td>
<td>Any age</td>
<td>Dome-shaped, regularly bordered, smooth, round, tan-dark brown papule Face, trunk, extremities, scalp NOT found on palms or soles</td>
<td>Melanocytes at dermal-epidermal junction; migration into dermis</td>
</tr>
<tr>
<td>Dermal</td>
<td>Adults</td>
<td>Soft, dome-shaped, skin-coloured to tan/brown papules or nodules Sites: face, neck</td>
<td>Melanocytes exclusively in dermis</td>
</tr>
</tbody>
</table>
Management
- new or changing pigmented lesions should be evaluated for atypical features which could indicate a melanoma
- excisional biopsy should be considered if the lesion demonstrates rapid change, asymmetry, varied colours, irregular borders and persistent pruritus or bleeding

HEMANGIOMAS

Clinical Feature
- red or blue subcutaneous mass that is soft/compressible, blanches with pressure; feels like a “bag of worms” when palpated

Pathophysiology
- benign vascular tumour
- includes: cavernous hemangioma, capillary/infantile hemangioma, spider hemangioma
Common Skin Lesions

Lipoma

Clinical Feature
- single or multiple non-tender subcutaneous tumours that are soft and mobile
- occurs most frequently on the trunk, and extremities but can be anywhere on the body

Pathophysiology
- adipocytes enclosed in a fibrous capsule

Epidemiology
- often solitary or few in number, if multiple can be associated with rare syndromes

Differential Diagnosis
- angiolipoma, liposarcoma

Investigations
- biopsy only if atypical features (painful, rapid growth, firm)

Management
- reassurance
- excision or liposuction only if desired for cosmetic purposes
## Acneiform Eruptions
### Acne Vulgaris/Common Acne

**Clinical Feature**
- a common inflammatory pilosebaceous disease categorized with respect to severity
  - Type I: comedonal, sparse, no scarring
  - Type II: comedonal, papular, moderate ± little scarring
  - Type III: comedonal, papular, and pustular, with scarring
  - Type IV: nodulocystic acne, risk of severe scarring
- sites of predilection: face, neck, upper chest, and back

**Pathophysiology**
- hyperkeratinization at the follicular ostia (opening) blocks the secretion of sebum leading to the formation of microcomedones
- androgens promote excess sebum production
- *Cutibacterium acnes* metabolize sebum to free fatty acids and produces pro-inflammatory mediators

**Epidemiology**
- age of onset in puberty (10-17 yr in females, 14-19 yr in males)
- in prepubertal children consider underlying hormonal abnormality (e.g. late onset congenital adrenal hyperplasia)
- incidence decreases in adulthood
- genetic predisposition: majority of individuals with cystic acne have parent(s) with history of severe acne

**Differential Diagnosis**
- folliculitis, keratosis pilaris (upper arms, face, thighs), perioral dermatitis, rosacea

</tr>
</tbody>
</table>
**Perioral Dermatitis**

**Clinical Feature**
- discrete erythematous micropapules that often become confluent, forming inflammatory plaques on perioral, perinasal, and periorbital skin
- commonly symmetrical, rim of sparing around vermillion border of lips

**Epidemiology**
- 15-40 yr old, occasionally in younger children
- predominantly females

**Differential Diagnosis**
- contact dermatitis, rosacea, acne vulgaris

**Management**
- avoid all topical steroids
- topical: metronidazole 0.75% gel or 0.75-1% cream to affected area bid
- systemic: tetracycline family antibiotic (utilized for its anti-inflammatory properties)
- occasional use of a non-steroidal anti-inflammatory cream (i.e. tacrolimus or pimecrolimus)

---

**Rosacea**

**Clinical Feature**
- dome-shaped inflammatory papules ± pustules
- flushing, non-transient erythema, and telangiectasia
- distribution: typically on central face including forehead, nose, cheeks, and chin; rarely on scalp, neck, and upper body
- characterized by remissions and exacerbations
- exacerbating factors: heat, cold, wind, sun, stress, drinking hot liquids, alcohol, spices
- all forms of rosacea can progress from mild to moderate to severe
- rarely in longstanding rosacea, signs of thickening, induration and lymphedema in the skin can develop
- phyma: a distinct swelling caused by lymphedema and hypertrophy of subcutaneous tissue, particularly affecting the nose (rhinophyma)
- ocular manifestations: blepharoconjunctivitis, keratitis, iritis

**Pathophysiology**
- unknown

**Epidemiology**
- although found in all skin types, highest prevalence in fair-skinned people
- 30-50 yr old; F:M

**Differential Diagnosis**
- acne vulgaris, seborrheic dermatitis, perioral dermatitis, contact dermatitis

**Management**
- trigger avoidance and daily sunscreen use for long-term management
- avoid topical corticosteroids
- telangiectasia: treated by physical ablation; electrical hyfrecators, vascular lasers, and intense pulsed light therapies
- phymas: treated by physical ablation or removal; paring, electrosurgery, cryotherapy, laser therapy (CO2, argon, Nd:YAG)

**Important Controversies Associated with Isotretinoin Therapy for Acne**

**Main Points:**
1. The evidence on whether isotretinoin causes depression and suicide is inconsistent; however, numerous controlled studies have shown an improvement in anxiety and depression scores in those taking isotretinoin.
2. There is no association between IBD and isotretinoin use. Only one study showed a significantly increased risk of UC. When considering using isotretinoin in a patient with IBD or with a strong family history, consider involving a gastroenterologist.

---

**Rosacea can be differentiated from acne by the absence of comedones, a predilection for the central face and symptoms of flushing**

**Guidelines for the Diagnosis of Rosacea**

**J Drugs Dermatol 2012;11(8):725-730**

Presence of one or more of the following primary features:
- Flushing (transient erythema)
- Nontransient erythema
- Papules and pustules
- Telangiectasia

May include one or more of the following secondary features:
- Burning or stinging
- Dry appearance
- Edema
- Phymatous changes
- Ocular manifestations
- Peripheral location
Dermatitis (Eczema)

Definition
• inflammation of the skin

Clinical Feature
• poorly demarcated erythematous patches or plaques
• symptoms include pruritus and pain
• acute dermatitis: papules, vesicles
• subacute dermatitis: scaling, crusting, excoriations
• chronic dermatitis: lichenification, xerosis, fissuring

Asteatotic Dermatitis

Clinical Feature
• diffuse, mild pruritic dermatitis secondary to dry skin
• very common in elderly, especially in the winter (i.e. “winter itch”) but starts in the fall
• shins predominate, looks like a “dried river bed”

Management
• skin rehydration with moisturizing routine ± corticosteroid creams

Atopic Dermatitis

Clinical Feature
• subacute and chronic eczematous reaction associated with prolonged severe pruritus
• distribution depends on age
• inflammation, lichenification, excoriations are secondary to relentless scratching
• atopic palms: hyperlinearity of the palms (associated with ichthyosis vulgaris)
• associated with: keratosis pilaris (hyperkeratosis of hair follicles, “chicken skin”), xerosis, occupational hand dryness
• associated with severe or poorly controlled psychosocial distress and psychiatric comorbidities

Epidemiology
• frequently affects infants, children, and young adults
• 10-20% of children in developed countries under the age of 5 are affected
• associated with personal or family history of atopy (asthma, hay fever), anaphylaxis, eosinophilia
• polygenic inheritance: one parent >60% chance for child; two parents >80% chance for child
• long-term condition with 1/3 of patients continuing to show signs of AD into adulthood

Pathophysiology
• a T-cell driven inflammatory process with epidermal barrier dysfunction

Investigations
• clinical diagnosis
• consider: skin biopsy, patch testing if allergic contact dermatitis is suspected

Management
• goal: reduce signs and symptoms, prevent or reduce recurrences/flares
• better outcome (e.g. less flare-ups, modified course of disease) if diagnosis made early
• avoid triggers of AD
• be vigilant for depressive symptoms and the possible need for psychiatric referral, especially among those with severe disease
• non-pharmacologic therapy
  • moisturizers
  • apply liberally and reapply at least twice a day with goal of minimizing xerosis
  • include in treatment of mild to severe disease as well as in maintenance therapy
  • bathe in plain warm water for a short period of time once daily followed by lightly but not completely drying the skin with a towel; immediately apply topical agents or moisturizers after this
  • use fragrance-free hypoallergenic non-soap cleansers
• pharmacologic therapy
  • topical corticosteroids
    • effective in reducing acute and chronic symptoms as well as prevention of flares
    • choice of steroid potency depends on age, body site, short vs. long-term use
    • apply 1 adult fingertip unit (0.5 g) to an area the size of 2 adult palms bid for acute flares
    • local side effects: skin atrophy, purpura, telangiectasia, striae, hypertrichosis, and acneiform eruption are all very rarely seen

Triggers for Atopic Dermatitis
• Irritants (detergents, solvents, clothing, water hardness)
• Contact allergens
• Environmental aeroallergens (e.g. dust mites)
• Inappropriate bathing habits (e.g. long hot showers)
• Sweating
• Microbes (e.g. S. aureus)
• Stress
Dermatitis (Eczema)

- topical calcineurin inhibitors
  - tacrolimus 0.03%, 0.1% (Protopic®) and pimecrolimus 1% (Elidel®)
- use as steroid-sparing agents in the long-term
- advantages over long-term corticosteroid use: sustained effect in controlling pruritus; no skin atrophy; safe for the face and neck
- apply 2x/d for acute flares, and 2-3x/wk to recurrent sites to prevent relapses
- local side effects: stinging, burning, allergic contact dermatitis
- U.S. black box warning of malignancy risk: rare cases of skin cancer and lymphoma reported; no causal relationship established, warning is discounted by both the Canadian Dermatology Association and the American Academy of Dermatology

Complications
- infections
- treatment of infections
- topical mupirocin, retapamulin, ozenoxacin or fusidic acid (Canada only, not available in US)
- oral antibiotics (e.g. cloxacillin, cephalixin) for widespread S. aureus infections

**Figure 5. Atopic dermatitis treatment algorithm**

**Contact Dermatitis**

**Clinical Feature**
- cutaneous inflammation caused by an external agent(s)

**Table 12. Contact Dermatitis**

Dermatitis (Eczema)

**Dyshidrotic Dermatitis**

**Clinical Feature**
- “tapioca pudding” papulovesicular dermatitis of hands and feet that coalesce into plaques, followed by painful fissuring
- acute stage often very pruritic
- secondary infections common
- lesions heal with desquamation and may lead to chronic lichenification
- sites: palms and soles ± dorsal surfaces of hands and feet

**Pathophysiology**
- unknown
- NOT caused by hyperhidrosis (excessive sweating)
- emotional stress may precipitate flares

**Management**
- topical: high potency corticosteroid with plastic cling wrap occlusion to increase penetration
- intralesional triamcinolone injection
- systemic:
  - prednisone in severe cases
  - allitretinoin (Toctino) for all types of chronic hand dermatitis, including dyshidrotic dermatitis
  - antibiotics for secondary S. aureus infection

**Nummular Dermatitis**

**Clinical Feature**
- nummular (coin-shaped), pruritic, dry, scaly, erythematous plaques
- often associated with atopic and dyshidrotic dermatitis
- secondary infection common

**Pathophysiology**
- little is known, but it is often accompanied by xerosis, which results from a dysfunction of the epidermal lipid barrier; this in turn can allow permeation of environmental agents, which can induce an allergic or irritant response

**Management**
- moisturization
- mid to high potency corticosteroid ointment twice daily

**Seborrheic Dermatitis**

**Clinical Feature**
- greasy, erythematous, yellow, scaling, minimally elevated papules and plaques in areas rich in sebaceous glands, can look moist and superficially eroded in flexural regions
- infants: “cradle cap”
- children: may be generalized with flexural and scalp involvement
- adults: diffuse involvement of scalp margin with yellow to white scales, pruritus, and underlying erythema
- sites: scalp, eyebrows, eyelashes, beard, glabella, post-auricular, over sternum, trunk, body folds, genitalia

**Pathophysiology**
- possible etiologic association with *Malassezia* spp. (yeast)

**Epidemiology**
- common in infants and adolescents
- increased incidence and severity in immunocompromised patients and Parkinson disease
- in adults can cause dandruff (pityriasis sicca)

**Management**
- face: ketoconazole (Nizoral®) cream daily or bid and/or mild steroid cream daily or bid
- scalp: salicylic acid in olive oil or Derma-Smoothe FS® lotion (peanut oil, mineral oil, fluocinolone acetonide 0.01%) to remove dense scales, 2% ketoconazole shampoo (Nizoral®), ciclopirox (Stieprox®) shampoo, selenium sulfide (e.g. Selsun®) or zinc pyrithione (e.g. Head and Shoulders®) shampoo, steroid lotion (e.g. betamethasone valerate 0.1% lotion bid)
Stasis Dermatitis

Clinical Feature
- erythematous, scaly, pruritic plaques in lower legs, particularly the medial ankle
- brown hemosiderin deposition, woody fibrosis, atrophy blanche, and lipodermatosclerosis in late stages
- usually bilateral, accompanied by swelling, oozing, crusting, may have accompanying varicosities

Pathophysiology
- chronic venous insufficiency leads to venous stasis
- surrounding soft tissue inflammation and fibrosis results

Investigations
- Doppler and colour-coded Duplex sonography if suspicious for DVT
- swab for bacterial culture if there is crusting

Management
- compression stockings
- rest and elevate legs (above the level of the heart)
- moisturizer to treat xerosis
- mid-high potency topical corticosteroids to control inflammation

Complications
- ulceration (common at medial malleolus), secondary bacterial infections

Lichen Simplex Chronicus

Clinical Feature
- well-defined plaque(s) of lichenified skin with increased skin markings ± excoriations
- common sites: neck, scalp, lower extremities, urogenital area
- often seen in patients with atopy

Pathophysiology
- skin hyperexcitable to itch, continued rubbing/scratching of skin results
- eventually lichenification occurs

Investigations
- if patient has generalized pruritus, rule out systemic cause: CBC with differential count, transaminases, bilirubin, renal and thyroid function tests, TSH, glucose, SPEP
- CXR if lymphoma suspected

Management
- antipruritics (e.g. antihistamines, topical or intralesional glucocorticoids, Unna boot)

Papulosquamous Diseases

Lichen Planus

Clinical Feature
- acute or chronic inflammation of mucous membranes or skin
- morphology: pruritic, well-demarcated, violaceous, polygonal, flat-topped papules
- common sites: wrists, ankles, mucous membranes in 60% (mouth, vulva, glans), nails, scalp
- distribution: symmetrical and bilateral
- Wickham's striae: reticulate white-grey lines over surface; pathognomonic but may not be present
- mucous membrane lesions: lacy, whitish reticular network, milky-white plaques/papules; increased risk of SCC in erosions and ulcers
- nails: longitudinal ridging; dystrophic; pterygium formation
- scalp: scarring alopecia with perifollicular hyperkeratosis and erythema
- spontaneously resolves but may last for wk, mo or yr (mouth and skin lesions)
- rarely associated with hepatitis C
- Koebner phenomenon

Pathophysiology
- autoimmune, antigen unknown
- lymphocyte activation leads to keratinocyte apoptosis

Epidemiology
- 1%, 30-60 yr, F>M
**Investigations**
- consider a skin biopsy
- hepatitis C serology if patient has risk factors

**Management**
- topical or intralesional corticosteroids
- short courses of oral prednisone (rarely)
- phototherapy or oral retinoids or systemic immunosuppressants (e.g. azathioprine, methotrexate, cyclosporine) for extensive or recalcitrant cases

---

**Pityriasis Rosea**

**Clinical Feature**
- acute, self-limiting eruption characterized by red, oval plaques/patches with central scale that does not extend to edge of lesion
- long axis of lesions follows skin tension lines (i.e. Langer’s Lines) parallel to ribs producing “Christmas tree” pattern on back
- varied degree of pruritus
- most start with a “herald” patch which precedes other lesions by 1-2 wk
- common sites: trunk, proximal aspects of arms and legs

**Etiology**
- suspected HHV-7 or HHV-6 reactivation

**Investigations**
- none required

**Management**
- none required; clears spontaneously in 6-12 wk
- symptomatic: topical glucocorticoids if pruritic, cool compresses, emollients

---

**Psoriasis**

**Classification**
1. plaque psoriasis  
2. guttate psoriasis  
3. erythrodermic psoriasis  
4. pustular psoriasis  
5. inverse psoriasis

**Pathophysiology**
- not fully understood, genetic and immunologic factors
- shortened keratinocyte cell cycle leads to Th1- and Th17-mediated inflammatory response

**Epidemiology**
- 1.5-2%, M=F
- all ages: peaks of onset: 20-30 yr old and 50-60 yr old
- polygenic inheritance: 8% with 1 affected parent, 41% with both parents affected
- risk factors: smoking, obesity, alcohol, drugs, infections, physical trauma (Koeber phenomenon)

**Differential Diagnosis**
- AD, mycosis fungoides (cutaneous T-cell lymphoma), seborrheic dermatitis, tinea, nummular dermatitis, lichen planus

**Investigations**
- biopsy (if atypical presentation, rarely needed)

**1. PLAQUE PSORIASIS**

**Clinical Feature**
- chronic and recurrent disease characterized by well-circumscribed erythematous papules/plaques with silvery-white scales
- often worse in winter (lack of sun)
- Auspitz sign: bleeds from minute points when scale is removed
- common sites: scalp, extensor surfaces of elbows and knees, trunk (especially buttocks), nails, pressure areas
Management
- depends on severity of disease, as defined by BSA affected or less commonly PASI
- mild (<3% BSA)
  - topical steroids, topical vitamin D3 analogues, or a combination of the two are first line
  - topical retinoid ± topical steroid combination, anthralin, and tar are also effective but tend to be less tolerated than first line therapies
  - emollients
  - phototherapy or systemic treatment may be necessary if the lesions are scattered or if it involves sites that are difficult to treat such as palms, soles, scalp, genitals
- moderate (3-10% BSA) to severe (>10% BSA)
  - goal of treatment is to attain symptom control that is adequate from patient’s perspective
  - phototherapy if accessible
  - systemic or biological therapy based on patient’s treatment history and comorbidities
  - topical steroid ± topical vitamin D3 analogue as adjunct therapy

</tbody>
</table>

*Brodalumab is a monoclonal antibody that targets the IL-17 receptor

*Can also be used to treat psoriatic arthritis

- biologics under study for treatment of psoriasis: risankizumab, tildrakizumab

---

Figure 6. Psoriasis distribution

Mechanism of Biologics
- mab = monoclonal antibody
- -cept = receptor
2. GUTTATE PSORIASIS (“DROP-LIKE”)

Clinical Feature
- discrete, scattered salmon-pink small scaling papules
- sites: diffuse, usually on trunk and legs, sparing palms and soles
- often antecedent streptococcal pharyngitis

Management
- UVB phototherapy, sunlight, lubricants, topical steroids
- penicillin V or erythromycin if Group A β-hemolytic Streptococcus on throat culture

3. ERYTHRODERMIC PSORIASIS

Clinical Feature
- generalized erythema (>90% of BSA) with fine desquamative scale on surface
- associated signs and symptoms: arthralgia, pruritus, dehydration, electrolyte imbalance
- aggravating factors: lithium, β-blockers, NSAIDs, antimalarials, phototoxic reaction, infection

Management
- IV fluids, monitor fluids and electrolytes, may require hospitalization
- treat underlying aggravating condition, sun avoidance
- cyclosporine, acitretin, methotrexate, UV, biologics

4. PUSTULAR PSORIASIS

Clinical Feature
- sudden onset of erythematous macules and papules which evolve rapidly into pustules, can be painful
- may be generalized or localized
- patient usually has a history of psoriasis; may occur with sudden withdrawal from steroid therapy

Management
- methotrexate, cyclosporine, acitretin, UV, biologics

5. INVERSE PSORIASIS

Clinical Feature
- erythematous plaques on flexural surfaces such as axillae, inframammary folds, gluteal fold, inguinal folds
- lesions may be macerated

Management
- low potency topical corticosteroids
- topical vitamin D derivatives (e.g. calcipotriene, calcitriol)
- topical calcineurin inhibitors (e.g. tacrolimus, pimecrolimus)

6. PSORIATIC ARTHRITIS

- 20-30% of patients with psoriasis also suffer from psoriatic arthritis
- psoriatic patients with nail or scalp involvement are at a higher risk for developing psoriatic arthritis
- see Rheumatology, RH24

---

**Vesiculobullous Diseases**

**Bullous Pemphigoid**

Clinical Feature
- chronic autoimmune bullous eruption characterized by pruritic, tense, subepidermal bullae on an erythematous or normal skin base
- can present as urticarial plaques without bullae
- common sites: flexor aspect of forearms, axillae, medial thighs, groin, abdomen, mouth in 33%

Pathophysiology
- IgG produced against dermal-epidermal basement membrane proteins (hemidesmosomes) leads to subepidermal bullae

Epidemiology
- mean age of onset: 60-80 yr old, F=M
Investigations
- immunofluorescence shows linear deposition of IgG and C3 along the basement membrane
- anti-basement membrane antibody (IgG) (pemphigoid antibody detectable in serum)

Prognosis
- heals without scarring, usually chronic
- rarely fatal

Management
- prednisone 0.5-1 mg/kg/d until clear, then taper ± steroid-sparing agents (e.g. azathioprine, cyclosporine, mycophenolate mofetil)
- topical potent steroids (clobetasol) may be as effective as systemic steroids in limited disease
- tetracycline ± nicotinamide is effective for some cases
- immunosuppressants such as azathioprine, mycophenolate mofetil, cyclosporine
- IVIg and plasmapheresis for refractory cases

Pemphigus Vulgaris

Clinical Feature
- autoimmune blistering disease characterized by flaccid, non-pruritic intraepidermal bullae/vesicles on an erythematous or normal skin base
- may present with erosions and secondary bacterial infection
- sites: mouth (90%), scalp, face, chest, axillae, groin, umbilicus
- Nikolsky’s sign: epidermal detachment with shear stress
- Asboe-Hansen sign: pressure applied to bulla causes it to extend laterally

Pathophysiology
- IgG against epidermal desmoglein-1 and -3 lead to loss of intercellular adhesion in the epidermis

Epidemiology
- 40-60 yr old, M:F, higher prevalence in Jewish, Mediterranean, Asian populations
- paraneoplastic pemphigus may be associated with thymoma, myasthenia gravis, malignancy, and use of D-penicillamine

Investigations
- immunofluorescence: shows IgG and C3 deposition intraepidermally
- circulating serum anti-desmoglein IgG antibodies

Prognosis
- lesions heal with hyperpigmentation but do not scar
- may be fatal unless treated with immunosuppressive agents

Management
- prednisone 1-2 mg/kg until no new blisters, then 1-1.5 mg/kg until clear, then taper ± steroid-sparing agents (e.g. azathioprine, cyclophosphamide, cyclosporine, IVIg, mycophenolate mofetil, rituximab)

Dermatitis Herpetiformis

Clinical Feature
- grouped papules/vesicles/urticarial wheals on an erythematous base, associated with intense pruritus, burning, stinging, excoriations
- lesions grouped, bilaterally symmetrical
- common sites: extensor surfaces of elbows/knees, sacrum, buttocks, scalp

Pathophysiology
- transglutaminase IgA deposits in the skin alone or in immune complexes leading to eosinophil and neutrophil infiltration
- 90% have HLA B8, DR3, DQWZ
- 90-100% associated with an often subclinical gluten-sensitive enteropathy (i.e. celiac disease)
- 30% have thyroid disease; increased risk of intestinal lymphoma in untreated comorbid celiac disease; iron/folate deficiency is common

Epidemiology
- 20-60 yr old, M:F = 2:1

Investigations
- biopsy
- immunofluorescence shows IgA deposits in perilesional skin

Management
- dapsone (sulfapyridine if contraindicated or poorly tolerated)
- gluten-free diet for life – this can reduce risk of lymphoma
Porphyria Cutanea Tarda

**Clinical Feature**
- skin fragility followed by formation of tense vesicles/bullae and erosions on photoexposed skin
- gradual healing to scars, milia
- periorbital violaceous discoloration, diffuse hypermelanosis, facial hypertrichosis
- common sites: light-exposed areas subjected to trauma, dorsum of hands and feet, nose, and upper trunk

**Pathophysiology**
- uroporphyrinogen decarboxylase deficiency leads to excess heme precursors
- can be associated with hemochromatosis, alcohol abuse, DM, drugs (estrogen therapy, NSAIDs), HIV, hepatitis C, increased Fe indices

**Epidemiology**
- 30-40 yr old, M>F

**Investigations**
- urine and 5% HCl shows orange-red fluorescence under Wood’s lamp (UV rays)
- 24 h urine has elevated uroporphyrins
- stool contains elevated coproporphyrins
- immunofluorescence shows IgE at dermal-epidermal junctions

**Management**
- discontinue aggravating substances (alcohol, estrogen therapy)
- phlebotomy to decrease body iron load
- low dose hydroxychloroquine

Drug Eruptions

**Exanthematous**

**EXANTHEMATOUS DRUG REACTION**

**Clinical Feature**
- morphology: erythematous macules and papules ± scale
- spread: symmetrical, trunk to extremities
- time course: 7-14 d after drug initiation, fades 7-14 d after withdrawal

**Epidemiology**
- most common cutaneous drug reaction; increased in presence of infections
- common causative agents: penicillin, sulfonamides, phenytoin

**Management**
- weigh risks and benefits of drug discontinuation
- antihistamines, emollients, topical steroids

**Drug Induced Hypersensitivity Syndrome (DIHS) / Drug Reaction with Eosinophilia and Systemic Symptoms (DRESS)**

**Clinical Feature**
- morphology: morbilliform rash involving face, trunk, arms; can have facial edema
- systemic features: fever, malaise, cervical lymphadenopathy, internal organ involvement (e.g. hepatitis, arthralgia, nephritis, pneumonitis, lymphadenopathy, hematologic abnormalities, thyroid abnormalities)
- spread: starts with face or periorbitally and spreads caudally; no mucosal involvement
- time course: onset 1-6 wk after first exposure to drug; persists wk after withdrawal of drug

**Epidemiology**
- rare: incidence varies considerably depending on drug
- common causative agents: anticonvulsants (e.g. phenytoin, phenobarbital, carbamazepine, lamotrigine), sulfonamides, and allopurinol
- 10% mortality if severe, undiagnosed, and untreated

**Management**
- discontinue offending drug ± prednisone 0.5mg/kg/d, consider cyclosporine in severe cases
- may progress to generalized exfoliative dermatitis/erythroderma if drug is not discontinued
**Urticarial**

**DRUG INDUCED URTICARIA AND ANGIOEDEMA**

**Clinical Feature**
- morphology: wheals lasting >24 h unlike non-drug induced urticaria, angioedema (face and mucous membranes)
- systemic features: may be associated with systemic anaphylaxis (bronchospasm, laryngeal edema, shock)
- time course: h-d after exposure depending on the mechanism

**Epidemiology**
- second most common cutaneous drug reaction
- common causative agents: penicillins, ACEI, analgesics/anti-inflammatories, radiographic contrast media

**Management**
- discontinue offending drug, treatment with antihistamines, steroids, epinephrine if anaphylactic

**SERUM SICKNESS-LIKE REACTION**

**Clinical Feature**
- morphology: symmetrical cutaneous eruption (usually urticarial)
- systemic features: malaise, low grade fever, arthralgia, lymphadenopathy
- time course: appears 1-3 wk after drug initiation, resolve 2-3 wk after withdrawal

**Epidemiology**
- more prevalent in kids (0.02-0.2%)
- common causative agents: cefaclor in kids; bupropion in adults

**Management**
- discontinue offending drug ± topical/oral corticosteroids

**Pustular**

**ACUTE GENERALIZED EXANTHEMATOUS PUSTULOSIS (AGEP)**

**Clinical Feature**
- morphology: extensive erythematous, edematous, and sterile pustules
- systemic features: high fever, leukocytosis with neutrophilia
- spread: starts in face and intertriginous areas, spreads to trunk and extremities
- time course: appears 1 wk after drug initiation, resolves 2 wk after withdrawal

**Epidemiology**
- rare: 1-5/million
- common causative agents: aminopenicillins, cephalosporins, clindamycin, calcium channel blockers

**Management**
- discontinue offending drug and systemic corticosteroids

**Bullous**

**STEVEN-JOHNSON SYNDROME (SJS)/TOXIC EPIDERMAL NECROLYSIS (TEN)**

**Clinical Feature**
- morphology: prodromal rash (morbilliform/targetoid lesions ± purpura, or diffuse erythema), confluence of flaccid blisters, positive Nikolsky sign (epidermal detachment with shear stress), full thickness epidermal loss; dusky tender skin, bullae, desquamation/skin sloughing, atypical targets
- classification: BSA with epidermal detachment: <10% in SJS, 10-30% in SJS/TEN overlap, and >30% in TEN
- spread: face and extremities; may generalize; scalp, palms, soles relatively spared; erosion of mucous membranes (lips, oral mucosa, conjunctiva, GU mucosa)
- systemic features: fever (higher in TEN), cytopenias, renal tubular necrosis/AKI, tracheal erosion, infection, contractures, corneal scarring, phimosis, vaginal synechiae
- time course: appears 1-3 wk after drug initiation; progression <4 d; epidermal regrowth in 3 wk
- can have constitutional symptoms: malaise, fever, hypotension, tachycardia

**Epidemiology**
- SJS: 1.2-6/million; TEN: 0.4-1.2/million
- risk factors: SLE, HIV/AIDS, HLA-B1502 (reaction most prevalent in East Asians, associated with carbamazepine), HLA-B5801 (reaction most prevalent in Asians and Caucasians, associated with allopurinol)
- common causative agents: drugs (allopurinol, anti-epileptics, sulfonamides, NSAIDs, cephalosporins) responsible in 50% of SJS and 80% of TEN; viral or mycoplasma infections
- prognosis: 5% mortality in SJS, 30% in TEN due to fluid loss and infection

**SCORTEN Score for TEN Prognosis**

One point for each of: age ≥40, malignancy, body surface area detached ≥10%, tachycardia ≥120 bpm, serum urea >10 mmol/L, serum glucose >14 mmol/L, serum bicarbonate <20 mmol/L

Used to determine appropriate clinical setting: score 0-1 can be treated in non-specialized wards; score ≥2 should be transferred to intensive care or burn unit

Score at admission is predictive of survival: 94% for 0-1, 87% for 2, 53% for 3, 25% for 4, and 17% for ≥5
Differential Diagnosis
- scarlet fever, phototoxic eruption, GVHD, SSSS, exfoliative dermatitis, AGEP, paraneoplastic pemphigus

Management
- discontinue offending drug
- admit to intermediate/intensive care/burn unit
- supportive care: IV fluids, electrolyte replacement, nutritional support, pain control, wound care, sterile handling, monitor for and treat infection
- IVlg or cyclosporine or etanercept

Other

FIXED DRUG ERUPTION

Clinical Feature
- morphology: sharply demarcated erythematous oval patches on the skin or mucous membranes
- spread: commonly face, mucosa, genitalia, acral; recurs in same location upon subsequent exposure to the drug (fixed location)

Epidemiology
- common causative agents: antimicrobials (tetracycline, sulphonamides), anti-inflammatories, psychoactive agents (barbiturates), phenolphthalein

Management
- discontinue offending drug ± prednisone 1mg/kg/d x 2 wk for generalized lesions ± potent topical corticosteroids for non-eroded lesions or antimicrobial ointment for eroded lesions

PHOTOSENSITIVITY REACTION

Clinical Feature
- phototoxic reaction: “exaggerated sunburn” (erythema, edema, vesicles, bullae) confined to sun-exposed areas
- photoallergic reaction: pruritic eczematous eruption with papules, vesicles, scaling, and crusting that may spread to areas not exposed to light

Pathophysiology
- phototoxic reaction: direct tissue injury
- photoallergic reaction: type IV delayed hypersensitivity

Epidemiology
- common causative agents: chlorpromazine, doxycycline, thiazide diuretics, procainamide

Management
- sun protection ± topical/oral corticosteroids

Heritable Disorders

Ichthyosis Vulgaris

Clinical Feature
- xerosis with fine scaling as well as large adherent scales (“fish-scales”)
- affects arms, legs, palms, soles, back, forehead, and cheeks; spares flexural creases
- improves in summer, with humidity, and as the child grows into adulthood

Pathophysiology
- genetic deficiency in filaggrin protein leads to abnormal retention of keratinocytes (hyperkeratosis)
- scaling without inflammation

Epidemiology
- 1:300 incidence
- autosomal dominant inheritance
- associated with AD and keratosis pilaris

Investigations
- electron microscopy: keratohyalin granules

Management
- immersion in bath and oils followed by an emollient cream, humectant cream, or creams/oil containing urea or α- or β-hydroxy acids
- intermittent systemic retinoids for severe cases
Neurofibromatosis (Type I; von Recklinghausen’s Disease)

Clinical Feature
- diagnostic criteria includes 2 or more of the following:
  1. more than 5 café-au-lait patches >1.5 cm in an adult or more than 5 café-au-lait macules >0.5 cm in a child <5 yr
  2. axillary or inguinal freckling
  3. iris hamartomas (Lisch nodules)
  4. optic gliomas
  5. neurofibromas
  6. distinctive bony lesion (sphenoid wing dysplasia or thinning of long bone cortex)
  7. first degree relative with neurofibromatosis Type I
- associated with pheochromocytoma, astrocytoma, bilateral acoustic neumomas, bone cysts, scoliosis, precocious puberty, developmental delay, and renal artery stenosis
- skin lesions less prominent in neurofibromatosis Type II (see Pediatrics, P79)

Pathophysiology
- autosomal dominant disorder with excessive and abnormal proliferation of neural crest elements (Schwann cells, melanocytes), high incidence of spontaneous mutation
- linked to absence of neurofibromin (a tumour suppressor gene)

Epidemiology
- incidence 1:3000

Investigations
- Wood’s lamp to detect café-au-lait macules in patients with pale skin

Management
- refer to orthopedics, ophthalmology, plastics, and psychology
- follow-up annually for brain tumours (e.g. astrocytoma)
- excise suspicious or painful lesions
- see Pediatrics, P79

Vitiligo

Clinical Feature
- primary pigmentary disorder characterized by depigmentation
- acquired destruction of melanocytes characterized by sharply marginated white patches
- associated with streaks of depigmented hair, chorioretinitis
- sites: extensor surfaces and periorificial areas (mouth, eyes, anus, genitalia)
- Koebner phenomenon, may be precipitated by trauma

Pathophysiology
- acquired autoimmune destruction of melanocytes

Epidemiology
- 1% incidence, polygenic
- 30% with positive family history

Investigations
- rule out associated autoimmune diseases: thyroid disease, pernicious anemia, Addison’s disease, Type I DM
- Wood’s lamp to detect lesions: illuminates UV light onto skin to detect amelanosis (porcelain white discoulouration)

Management
- sun avoidance and protection
- topical calcineurin inhibitor (e.g. tacrolimus, pimecolimus) or topical corticosteroids
- PUVA or NB-UVB
- “bleaching” normal pigmented areas (i.e. monobenzyl ether of hydroquinone 20%) if widespread loss of pigmentation

Interventions for Vitiligo
Cochrane Database Syst Rev 2015;2:CD003263
Purpose: To assess the effects of existing interventions used in the management of vitiligo.
Study: Systematic review of RCTs assessing the effects of vitiligo treatments (topical treatments, light therapies, oral treatments, surgical method). Primary outcomes were quality of life and >75% re-pigmentation adverse effects.
Results: Ninety-six RCTs with 4512 participants were deemed eligible, of which only 25 reported on the primary outcomes and were finally included. Re-pigmentation was better with combination therapy (calcipotriol plus PUVA, than PUVA alone, hydrocortisone-17-butyrate plus excimer laser vs. excimer laser alone; oral minipulse of prednisolone (OMP) plus narrowband UVB (NB-UVB) vs. OMP alone; azathioprine with PUVA vs. PUVA alone; 8-methoxypsoralen (8-MOP) plus sunlight versus psoralen). A non-significant increase in proportion of participants with >75% re-pigmentation was noted in favour of NB-UVB compared to PUVA. Compared to PUVA, the NV-UVB group reported lower incidences of nausea and erythema, but not itching.
Conclusions: Some studies support existing therapies for vitiligo management, but follow-up is needed to assess permanence of re-pigmentation and higher quality RCTs need to be conducted.
Infections

Figure 7. Layers of skin affected by bacterial infections

**Bacterial Infections**

**EPIDERMIS**

**IMPETIGO**

**Clinical Feature**
- acute purulent infection which appears vesicular; progresses to golden yellow “honey-crusted” lesions surrounded by erythema
- can present with bullae
- common sites: face, arms, legs, and buttocks

**Etiology**
- GAS, S. aureus, or both

**Epidemiology**
- preschool and young adults living in crowded conditions, poor hygiene, neglected minor trauma

**Differential Diagnosis**
- infected eczema, HSV, VZV

**Investigations**
- Gram stain and culture of lesion fluid or biopsy

**Management**
- remove crusts, use saline compresses, and topical antiseptic soaks bid
- topical antibacterials (e.g. 2% mupirocin or fusidic acid (Canada only) tid; continue for 7-10 d after resolution)
- systemic antibiotics (e.g. cloxacillin or cepalexin for 7-10 d)
DERMIS

Dermatophytoses

Clinical Feature
- infection of skin, hair, and nails caused by dermatophytes (fungi that live within the epidermal keratin or hair follicle and do not penetrate into deeper structures)

Pathophysiology
- digestion of keratin by dermatophytes results in scaly skin, broken hairs, crumbling nails/onycholysis

Etiology
- Trichophyton, Microsporum, Epidermophyton species (Pityrosporum is a superficial yeast and not a dermatophyte)

Investigations
- skin scrapings, hair, and/or nail clippings analyzed with potassium hydroxide (KOH) prep to look for hyphae and mycelia

Management
- topicals as first line agents for tinea corporis/cruris and tinea pedis (interdigital type): clotrimazole, or terbinafine or ciclopirox olamine cream applied bid
- oral therapy is indicated for onychomycosis or tinea capitis: terbinafine (Lamisil® – liver toxicity, CYP2D6 inhibitor) or itraconazole (Sporanox® – CYP3A4 inhibitor, liver toxicity)
Table 18. Different Manifestations of Dermatophyte Infection

<td>AD, contact dermatitis, granuloma annulare, psoriasis</td>
<td>Same as for tinea corporis</td>
</tr>
<tr>
<td><strong>Tinea Unguim</strong></td>
<td>Crumbling, distally dystrophic nails; yellowish, opaque with subungual hyperkeratotic debris Toenail infections usually precede fingernail infections T. rubrum (90% of all toenail infections)</td>
<td>Psoriasis, lichen planus, contact dermatitis, traumatic onychodystrophies, bacterial infection</td>
<td>Microscopic examinations of KOH prep of scales from subungual scraping shows hyphae Culture of subungual scraping or nail clippings on Sabouraud's agar PAS stain of nail clipping by pathology</td>
</tr>
</tbody>
</table>

Parasitic Infections

**SCABIES**

**Clinical Feature**
- characterized by superficial burrows, intense pruritus (especially nocturnal), and secondary infection
- primary lesion: superficial linear burrows; inflammatory papules and nodules in the axilla and groin
- secondary lesion: small urticarial crusted papules, eczematous plaques, excoriations
- common sites: axillae, groin, buttocks, hands/feet (especially web spaces), sparing of head and neck (except in infants)

**Pathophysiology**
- scabies mite remains alive 2-3 d on clothing/sheets
- incubation of 1 mo, then pruritus begins
- re-infection followed by hypersensitivity in 24 h

**Etiology**
- *Sarcoptes scabiei* (a mite)
- risk factors: sexual promiscuity, crowding, poverty, nosocomial, immunocompromised
**Differential Diagnosis**
- asteatotic eczema, dermatitis herpetiformis, lichen simplex chronicus (neurodermatitis)

**Investigations**
- microscopic examination of root and content of burrow and mineral oil mount for mite, eggs, feces
- skin biopsy may sometimes show scabies mite

**Management**
- bathe, then apply permethrin 5% cream (i.e. Nix*) from neck down to soles of feet (must be left on for 8-14 h and requires second treatment 7 d after first treatment)
- change underwear and linens; wash twice with detergent in hot water cycle then machine dry
- treat family and close contacts
- pruritus may persist for 2-3 wk after effective treatment due to prolonged hypersensitivity reaction
- mid potency topical steroids and antihistamines for symptom management

**LICE (PEDICULOSIS)**

**Clinical Feature**
- intensely pruritic, red excoriations, morbilliform rash, caused by louse (a parasite)
- scalp lice: nits (i.e. louse eggs) on hairs; red, excoriated skin with secondary bacterial infection, lymphadenopathy
- pubic lice: nits on hairs; excoriations
- body lice: nits and lice in seams of clothing; excoriations and secondary infection mainly on shoulders, belt-line, and buttocks

**Etiology**
- *Phthirus pubis* (pubic), *Pediculus humanus capitis* (scalp), *Pediculus humanus humanus* (body): attaches to body hair and feeds on the nearby body site
- can transmit infectious agents (e.g. *Bartonella Quintana*, *Rickettsia prowazekii*)

**Differential Diagnosis**
- bacterial infection of scalp, seborrheic dermatitis

**Diagnosis**
- lice visible on inspection of affected area or clothing seams

**Management**
- permethrin 1% (Nix* cream rinse) (ovicidal) or permethrin 1% (RC & Cor*, Kwellada-P* shampoo)
- comb hair with fine-toothed comb using dilute vinegar solution to remove nits
- repeat in 7 d after first treatment
- shave hair if feasible, change clothing and linens; wash with detergent in hot water cycle then machine dry

**BED BUGS (HEMIPTERA)**

**Clinical Feature**
- burning wheals, turning to firm papules, often in groups of three – “breakfast, lunch and dinner” – in areas with easy access (face, neck, arms, legs, hands)

**Etiology**
- caused by Cimex lectularius, a small insect that feeds mainly at night (hides in crevices in walls and furniture during the day)

**Differential Diagnosis**
- dermatitis herpetiformis, drug eruptions, ecthyma, other insect bites, scabies

**Investigations**
- none required, but lesional biopsy can confirm insect bite reaction

**Management**
- professional fumigation
- topical steroids and oral H1-antagonists for symptomatic relief
- definitive treatment is removal of clutter in home and application of insecticides to walls and furniture
HERPES SIMPLEX

Clinical Feature
- herpetiform (i.e. grouped) vesicles on an erythematous base on skin or mucous membranes
- transmitted via contact with erupted vesicles or via asymptomatic viral shedding
- primary
  - children and young adults
  - usually asymptomatic; may have high fever, regional lymphadenopathy, malaise
  - followed by antibody formation and latency of virus in dorsal nerve root ganglion
- secondary
  - recurrent form seen in adults; much more common than primary
  - prodrome: tingling, pruritus, pain
  - triggers for recurrence: fever, excess sun exposure, physical trauma, menstruation, emotional stress, URTI
- complications: dendritic corneal ulcer, EM, herpes simplex encephalitis (infants at risk), HSV infection on AD causing Kaposi’s varicelliform eruption (eczema herpeticum)
- two biologically and immunologically different subtypes: HSV-1 and HSV-2
  - HSV-1
    - typically “cold sores” (grouped vesicles at the mucocutaneous junction which quickly burst)
    - recurrent on face, lips, and hard palate, but NOT on soft, non-keratinized mucous membranes (unlike aphthous ulcers)
  - HSV-2
    - usually sexually transmitted; incubation 2-20 d
    - gingivostomatitis: entire buccal mucosa involved with erythema and edema of gingiva
    - vulvovaginitis: edematous, erythematous, extremely tender, profuse vaginal discharge
    - urethritis: watery discharge in males
    - recurrent on vulva, vagina, penis for 5-7 d
    - differential diagnosis of genital ulcers: Candida balanitis, chancroid, syphilitic chancres

Investigations
- Tzanck smear with Giemsa stain shows multinucleated giant epithelial cells
- viral culture, electron microscopy, and direct fluorescence antibody test of specimen taken from the base of a relatively new lesion
- serologic testing for antibody for current or past infection if necessary

Management
- HSV-1
  - treat during prodrome to prevent vesicle formation
  - topical antiviral (Zovirax®/Xerese®) cream, apply 5-6x/d x 4-7 d for facial/genital lesions
  - oral antivirals (e.g. acyclovir, famciclovir, valacyclovir) are far more effective and have an easier dosing schedule than topicals
- HSV-2
  - rupture vesicle with sterile needle if you wish to culture it
  - wet dressing with aluminum subacetate solution, Burrow’s compression, or betadine solution
  - 1st episode: acyclovir 200 mg PO 5x/d x 10 d
    - maintenance: acyclovir 400 mg PO bid
  - famciclovir and valacyclovir may be substituted and have better enteric absorption and less frequent dosing
  - in case of herpes genitalis, look for and treat any other STIs
  - for active lesions in pregnancy, see Obstetrics, OB29

HERPES ZOSTER (SHINGLES)

Clinical Feature
- unilateral dermatomal eruption occurring 3-5 d after pain and paresthesia of that dermatome
- vesicles, bullae, and pustules on an erythematous, edematous base
- lesions may become eroded/ulcerated and last days to weeks
- pain can be pre-herpetic, synchronous with rash, or post-herpetic
- severe post-herpetic neuralgia often occurs in elderly
- Hutchinson’s sign: shingles on the tip of the nose signifies ocular involvement
  - shingles in this area involves the nasociliary branch of the ophthalmic branch of the trigeminal nerve (V1)
- distribution: thoracic (50%), trigeminal (10-20%), cervical (10-20%); disseminated in HIV

Etiology
- caused by reactivation of VZV
- risk factors: immunosuppression, old age, occasionally associated with hematologic malignancy
Infections

**Differential Diagnosis**
- before thoracic skin lesions occur, must consider other causes of chest pain
- contact dermatitis, localized bacterial infection, zosteriform HSV (more pathogenic for the eyes than VZV)

**Investigations**
- none required, but can do Tzanck test, direct fluorescence antibody test, or viral culture to rule out HSV

**Prevention**
- routine vaccination in 50+ yr old with Shingrix® (recombinant zoster vaccine) preferred to in 60+ yr old with Zostavax® (live zoster vaccine)

**Management**
- compress with normal saline, Burow’s or betadine solution
- oral antivirals: famciclovir, valacyclovir, or acyclovir for 7 d; must initiate within 72 h to be of benefit
- analgesia: NSAIDs, acetaminophen for mild-moderate pain; opioids if severe
- post-herpetic neuralgia: TCAs, anticonvulsants (gabapentin, pregabalin)

### MOLLUSCUM CONTAGIOSUM

**Clinical Feature**
- discrete dome-shaped and umbilicated pearly, white papules caused by DNA Pox virus (Molluscum contagiosum virus)
- common sites: eyelids, beard (likely spread by shaving), neck, axillae, trunk, perineum, buttocks

**Etiology**
- virus is spread via direct contact, auto-inoculation, sexual contact
- common in children and sexually active young adults (giant molluscum and severe cases can be seen in the setting of HIV)
- virus is self-limited and can take 1-2 yr to resolve

**Investigations**
- none required, however can biopsy to confirm diagnosis

**Management**
- topical cantharidin (a vesicant)
- cryotherapy
- curettage
- topical retinoids
- Aldara® (imiquimod): immune modulator that produces a cytokine inflammation

### WARTS (VERRUCA VULGARIS) (HUMAN PAPILLOMAVIRUS INFECTIONS)

**Table 19. Different Manifestations of HPV Infection**

<table>
<thead>
<tr>
<th>Definition and Clinical Features</th>
<th>Differential Diagnosis</th>
<th>Distribution</th>
<th>HPV Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Verruca Vulgaris</strong> (Common Warts)</td>
<td>Hyperkeratotic, elevated discrete epithelial growths with papillated surface caused by HPV</td>
<td>Molluscum contagiosum, seborrheic keratosis</td>
<td>Located at trauma sites: fingers, hands, knees of children and teens</td>
</tr>
<tr>
<td><strong>Verruca Plantaris</strong> (Plantar Warts) and <strong>Verruca Palmaris</strong> (Palmar Warts)</td>
<td>Hyperkeratotic, shiny, sharply marginated growths Paring of surface reveals red-brown specks (capillaries), interruption of epidermal ridges</td>
<td>May need to scrape (“pare”) lesions to differentiate wart from callosus and corn</td>
<td>Located at pressure sites: metatarsal heads, heels, toes</td>
</tr>
<tr>
<td><strong>Verruca Planae</strong> (Flat Warts)</td>
<td>Multiple discrete, skin coloured, flat topped papules grouped or in linear configuration Common in children</td>
<td>Syringoma, seborrheic keratosis, molluscum contagiosum, lichen planus</td>
<td>Sites: face, dorsa of hands, shins, knees</td>
</tr>
<tr>
<td><strong>Condyloma Acuminata</strong> (Genital Warts)</td>
<td>Skin-coloured pinhead papules to soft cauliflower like masses in clusters Can be asymptomatic, lasting months to years Highly contagious, transmitted sexually and non-sexually (e.g. Koebner phenomenon via scratching, shaving), and can spread without clinically apparent lesions Investigations: acetowhitenening (subclinical lesions seen with 5% acetic acid x 5 min and hand lens) Complications: fairy-ring warts (satellite warts at periphery of treated area of original warts)</td>
<td>Condyloma lata (secondary syphilitic lesion, dark field strongly +ve), molluscum contagiosum</td>
<td>Sites: genitalia and perianal areas</td>
</tr>
</tbody>
</table>
Treatment for Warts
- first line therapies
  - salicylic acid preparations (patches, solutions, creams, ointments), cryotherapy, topical cantharidin (Cantharone®)
- second line therapies
  - topical imiquimod, topical 5-fluorouracil, topical tretinoin, podophyllotoxin
- third line therapies
  - curettage, cautery, surgery for non plantar warts, CO₂ laser, oral cimetidine (particularly children), intralesional bleomycin (plantar warts), trichloroacetic acid, diphencyprone
- other viruses associated with skin changes, such as measles, roseola, fifth disease, etc.
  - see Pediatrics, Pediatric Exanthems, P53

Yeast Infections

CANDIDIASIS

Etiology
- many species of Candida (70-80% of infections are from Candida albicans)
- opportunistic infection in those with predisposing factors (e.g. trauma, malnutrition, immunodeficiency)

Candidal Paronychia
- clinical feature: painful red swelling of periungual skin
- management: topical agents not as effective; oral antifungals recommended

Candidal Intertrigo
- clinical feature: macerated/eroded erythematous patches that may be covered with papules and pustules, located in intertriginous areas (often under breast, groin, or interdigitally)
- peripheral “satellite” pustules
- starts as non-infectious maceration from heat, moisture, and friction
- predisposing factors: obesity, DM, systemic antibiotics, immunosuppression, malignancy
- management: keep area dry, terbinafine, ciclopirox ointment, ketoconazole/clotrimazole cream bid until rash clears

PITYRIASIS (TINEA) VERSICOLOR

Clinical Feature
- asymptomatic superficial fungal infection with brown/white scaling macules
- affected skin darker than surrounding skin in winter, lighter in summer (does not tan)
- common sites: upper chest and back

Pathophysiology
- microbe produces azelaic acid → inflammatory reaction inhibiting melanin synthesis yielding variable pigmentation
- affinity for sebaceous glands; require fatty acids to survive

Etiology
- Pityrosporum ovale (Malassezia furfur)
- also associated with folliculitis and seborrheic dermatitis
- predisposing factors: summer, tropical climates, excessive sweating, Cushing’s syndrome, prolonged corticosteroid use

Investigations
- clinical diagnosis but can perform microscopic examination, KOH prep of scales for hyphae and spores

Management
- ketoconazole shampoo or cream daily
- topical terbinafine or ciclopirox ointment bid
- systemic fluconazole or itraconazole for 7 d if extensive

Sexually Transmitted Infections

SYPHILIS

Clinical Feature
- characterized initially by a painless ulcer (chancre)
- following inoculation, systemic infection with secondary and tertiary stages

Etiology
- Treponema pallidum
- transmitted sexually, congenitally, or rarely by transfusion
### Table 20. Stages of Syphilis

<table>
<thead>
<tr>
<th>Clinical Feature</th>
<th>Investigations</th>
<th>Management</th>
</tr>
</thead>
</table>
| **Primary Syphilis** | Single red, indurated, painless chancre, that develops into painless ulcer with raised border and scanty serous exudate  
Chancre develops at site of inoculation after 3 wk of incubation and heals in 4-6 wk; chancre may also develop on lips or anus  
Regional non-tender lymphadenopathy appears <1 wk after onset of chancre  
DDx: chancroid (painful), HSV (multiple lesions) | CANNOT be based on Clinical Feature alone  
VDRL negative – repeat weekly for 1 mo  
FTA-ABS test has greater sensitivity and may detect disease earlier in course  
Dark field examination – spirochete in chancre fluid or lymph node aspirate | Penicillin G, 2.4 million units IM, single dose |
| **Secondary Syphilis** | Presents 2-6 mo after primary infection (patient may not recall presence of primary chancre)  
Associated with generalized lymphadenopathy, splenomegaly, headache, chills, fever, arthralgias, myalgias, malaise, photophobia  
Lesions heal in 1-5 wk and may recur for 1 yr  
3 types of lesions:  
1. Macules and papules: flat top, scaling, non-pruritic, sharply defined, circular/annular rash (DDx: pityriasis rosea, tinea corporis, drug eruptions, lichen planus)  
2. Condyloma lata: wart-like moist papules around genital/perianal region  
3. Mucous patches: macerated patches mainly found in oral mucosa | VDRL positive  
FTA-ABS +ve; −ve after 1 yr following appearance of chancre  
Dark field +ve in all secondary | As for primary syphilis |
| **Tertiary Syphilis** | Extremely rare  
3-7 yr after secondary  
Main skin lesion: “Gumma” – a granulomatous non-tender nodule | As in primary syphilis, VDRL can be falsely negative | Penicillin G, 2.4 million units IM weekly x 3 wk |

### GONOCOCCEMIA

**Clinical Feature**
- disseminated gonococcal infection
- hemorrhagic, tender, pustules on a purpuric/petechial background
- common sites: distal aspects of extremities
- associated with fever, arthritis, urethritis, proctitis, pharyngitis, and tenosynovitis
- neonatal conjunctivitis if infected via birth canal

**Etiology**
- *Neisseria gonorrhoeae*

**Investigations**
- requires high index of clinical suspicion because tests are often negative
- bacterial culture of blood, joint fluid, and skin lesions
- joint fluid cell count and Gram stain

**Management**
- notify Public Health authorities
- screen for other STIs
- cefixime 400 mg PO (drug of choice) or ceftriaxone 1 g IM

### HSV
- see Viral Infections, D29

### HPV
- see Viral Infections, D29
Pre-Malignant Skin Conditions

Actinic Keratosis (Solar Keratosis)

Clinical Feature
- ill-defined, scaly, erythematous papules or plaques on a background of sun-damaged skin (solar heliosis)
- sandpaper-like, gritty sensation felt on palpation, often easier to appreciate on palpation rather than inspection
- sites: areas of sun exposure (face, ears, scalp if bald, neck, sun-exposed limbs)

Pathophysiology
- UV radiation damage to keratinocytes from repeated sun exposure (especially UVB)
- risk of transformation of AK to SCC (~1/1000), but higher likelihood if AK is persistent
- UV-induced p53 gene mutation
- risk factors: increased age, light skin/eyes/hair, immunosuppression, syndromes such as albinism or xeroderma pigmentosum
- risk factors for malignancy: immunosuppression, history of skin cancer, persistence of the AK

Epidemiology
- common with increasing age, outdoor occupation, M>F
- skin phototypes I-III, rare in darker skin as melanin is protective

Differential Diagnosis
- SCC in situ, superficial BCC, seborrheic keratosis, cutaneous lupus erythematosus

Investigations
- biopsy lesions that are refractory to treatment

Management
- destructive: cryotherapy, electrodessication, and curettage
- topical pharmacotherapy (mechanism: destruction of rapidly growing cells or immune system modulation)
  - topical 5-fluorouracil cream (for 2-4 wk), imiquimod 5% (2x/wk for 16 wk), imiquimod 3.75% (daily for 2 wk then none for 2 wk then daily for 2 wk), ingenol Mbutate gel 0.015% (daily for 3 d on the head and neck), ingenol mebutate 0.05% gel (daily for 2 d on the body)
- photodynamic therapy
- excision

Leukoplakia

Clinical Feature
- a morphologic term describing homogeneous or speckled white plaques with sharply demarcated borders
- sites: oropharynx, most often floor of the mouth, soft palate, and ventral/lateral surfaces of the tongue

Pathophysiology
- precancerous or premalignant condition
- oral form is strongly associated with tobacco use and alcohol consumption

Epidemiology
- 1-5% prevalence in adult population after 30 yr of age; peak at age 50
- M>F, fair-skinned
- most common oral mucosal premalignant lesion

Differential Diagnosis
- lichen planus, oral hairy leukoplakia, white sponge nevus

Investigations
- biopsy is mandatory due to risk of malignancy

Management
- low risk sites on buccal/labial mucosal or hard palate: eliminate carcinogenic habits, smoking cessation, follow-up
- moderate/dysplastic lesions: excision, cryotherapy
Malignant Skin Tumours

Non-Melanoma Skin Cancers

BASAL CELL CARCINOMA

Subtypes
- noduloulcerative (typical)
  - skin-coloured papule/nodule with rolled, translucent (“peary”) telangiectatic border, and depressed/eroded/ulcerated centre
- pigmented variant
  - flecks of pigment in translucent lesion with surface telangiectasia
  - may mimic malignant melanoma
- superficial variant
  - flat, tan to red-brown plaque, often with scaly, pearly border, and fine telangiectasia at margin
  - least aggressive subtype
- sclerosing (morpheaform) variant
  - flesh/yellowish-coloured, shiny papule/plaque with indistinct borders, indurated

Pathophysiology
- malignant proliferation of basal keratinocytes of the epidermis
  - low grade cutaneous malignancy, locally aggressive (primarily tangential growth), rarely metastatic
  - usually due to UVB light exposure, therefore >80% on face
  - may also occur in previous scars, radiation, trauma, arsenic exposure, or genetic predisposition (Gorlin Syndrome)

Epidemiology
- most common malignancy in humans
- 75% of all malignant skin tumours >40 yr, increased prevalence in the elderly
- M>F, skin phototypes I and II, chronic cumulative sun exposure, ionizing radiation, immunosuppression, arsenic exposure

Differential Diagnosis
- benign: sebaceous hyperplasia, intradermal melanocytic nevus, dermatofibroma
- malignant: nodular malignant melanoma, SCC

Management
- imiquimod 5% cream (Aldara®) or cryotherapy is indicated for superficial BCCs on the trunk
- 5-fluorouracil and photodynamic therapy can also be used for superficial BCCs
- shave excision and electrodesication and curettage for most types of BCCs, not including morpheaform
- Mohs surgery: microscopically controlled, minimally invasive, stepwise excision for lesions on the face or in areas that are difficult to reconstruct
- radiotherapy used in advanced cases of BCC
- vismodegib is approved for metastatic BCC, also in syndromes characterized by multiple BCCs (Gorlin Syndrome)
- follow-up for new primary disease or recurrence
- 95% cure rate if lesion <2 cm in diameter or if treated early

BOWEN’S DISEASE (SQUAMOUS CELL CARCINOMA IN SITU)

Clinical Feature
- sharply demarcated erythematous patch/thin plaque with scale and/or crusting
- often 1-3 cm in diameter and found on the skin and mucous membranes
- evolves to SCC in 10-20% of cutaneous lesions and >20% of mucosal lesions

Management
- same as for BCC
- biopsy required for diagnosis
- topical 5-fluorouracil (Efudex®) or imiquimod (Aldara®) used if extensive and as a tool to identify margins of poorly defined tumours
- cryosurgery
- shave excision with electrodesicication and curettage

Workup/Investigations of BCC and Other NMSCs
- History: duration, growth rate, family/personal Hx of skin cancer, prior therapy to the lesion
- Physical: location, size, whether circumscribed, tethering to deep structures, full skin exam, lymph node exam
- Biopsy: if shallow lesion, can do shave biopsy; otherwise punch or excisional biopsy may be more appropriate

Surgical Margins
- Smaller lesions: electrodesicication and curettage with 2-3 mm margin of normal skin
- Deep infiltrating lesions: surgical excision with 3-5 mm margins beyond visible and palpable tumour border, which may require skin graft or flap; or Mohs surgery, which conserves tissue and does not require margin control
SQUAMOUS CELL CARCINOMA

Clinical Feature
- hyperkeratotic indurated, pink/red/skin-coloured papule/plaque/nodule with surface scale/crust ± ulceration
- more rapid enlargement than BCC
- exophytic (grows outward), may present as a cutaneous horn
- sites: face, ears, scalp, forearms, dorsum of hands

Pathophysiology
- malignant neoplasm of keratinocytes (primarily vertical growth)
- predisposing factors include: cumulative UV radiation, PUVA, ionizing radiation therapy/exposure, chemical carcinogens (such as arsenic, tar, and nitrogen mustards), HPV 16, 18, immunosuppression
- may occur in previous scar (SCC more commonly than BCC)

Epidemiology
- second most common type of cutaneous neoplasm
- primarily on sun-exposed skin in the elderly, M>F, skin phototypes I and II, chronic sun exposure
- in organ transplant recipients, SCC is most common cutaneous malignancy, with increased mortality as compared to non-immunocompromised population

Differential Diagnosis
- benign: nummular eczema, psoriasis, irritated seborrheic keratosis
- pre-malignant: Actinic Keratosis, Bowenoid papulosis
- malignant: keratoacanthoma, Bowen's disease, BCC, amelanotic melanoma

Management
- surgical excision with primary closure, skin flaps or grafting
- Mohs surgery
- lifelong follow-up (more aggressive treatment than BCC)
- radiation therapy

Prognosis
- good prognostic factors: early treatment, negative margins, and small size of lesion
- SCCs that arise from AK metastasize less frequently (~1%) than other SCCs arising de novo in old burns (2-5% of cases)
- overall control is 75% over 5 yr, rate of metastasis from primary SCC is 2-5%
- metastasis rates are higher if diameter >2 cm, depth >4 mm, recurrent, involvement of bone/muscle/nerve, location on scalp/ears/nose/lips, immunosuppressed, caused by arsenic ingestion, or tumour arose from scar/chronic ulcer/burn/genital tract/sinus tract

KERATOACANTHOMA

Clinical Feature
- rapidly growing, firm, dome-shaped, erythematous or skin-coloured nodule with central keratin-filled crater, resembling an erupting volcano
- may spontaneously regress within a year, leaving a scar
- sites: sun-exposed skin

Pathophysiology
- epithelial neoplasm with atypical keratinocytes in epidermis
- low grade variant of SCC

Etiology
- HPV, UV radiation, chemical carcinogens (tar, mineral oil)

Epidemiology
- >50 yr, rare <20 yr

Differential Diagnosis
- treat as SCC until proven otherwise
- nodular BCC, Merkel cell carcinoma, hypertrophic solar keratosis, verruca vulgaris

Management
- surgical excision or saucerization (shave biopsy) followed by electrodesiccation of the base, treated similarly to SCC
- intralosomal methotrexate injection
Malignant Melanoma

Clinical Feature
- malignant characteristics of a mole: "ABCDE" mnemonic
- sites: skin, mucous membranes, eyes, CNS
- ~2/3 arise de novo without an associated nevus

Clinical Subtypes of Malignant Melanoma
- lentigo maligna
  - malignant melanoma in situ (normal and malignant melanocytes confined to the epidermis)
  - 2-6 cm, tan/brown/black uniformly flat macule or patch with irregular borders
  - lesion grows radially and produces complex colours
  - often seen in the elderly
  - 10% evolve to lentigo maligna melanoma
- lentigo maligna melanoma (15% of all melanomas)
  - older individuals, ~7th decade
  - malignant melanocytes invading into the dermis
  - associated with pre-existing solar lentigo, not pre-existing nevi
  - flat, brown, stain-like, gradually enlarging with loss of skin surface markings
  - with time, colour changes from uniform brown to dark brown with black and blue
  - found on all skin surfaces, especially those often exposed to sun, such as the face and hands
- superficial spreading melanoma (60-70% of all melanomas)
  - atypical melanocytes initially spread laterally in epidermis then invade the dermis
  - irregular, indurated, enlarging plaques with red/white/blue discoulouration, focal papules or nodules
  - ulcerate and bleed with growth
  - subtype most likely associated with pre-existing nevus
- nodular melanoma (30% of all melanomas)
  - atypical melanocytes that initially grow vertically with little lateral spread
  - uniformly ulcerated, blue-black, and sharply delineated plaque or nodule
  - rapidly fatal
  - may be pink or have no colour at all, this is called an amelanotic melanoma
  - EFG = elevated, firm, growing
- acral lentiginous melanoma (5% of all melanomas)
  - ill-defined dark brown, blue-black macule
  - palmar, plantar, subungual skin
  - melanomas on mucous membranes have poor prognosis

Pathophysiology
- malignant neoplasm of pigment-forming cells (melanocytes and nevus cells)

Epidemiology
- incidence: 1/75 (Canada), 1/50 (US)
- risk factors: increasing age, fair skin, red hair, positive personal/family history, familial dysplastic nevus syndrome, 1 large congenital nevus (>20 cm), any dysplastic nev, >50 common nevi, immunosuppression, sun exposure with sunburns, tanning beds
- most common sites: back (M), calves (F)
- worse prognosis if: male, on scalp, hands, feet, late lesion, no pre-existing nevus present

Differential Diagnosis
- benign: nevi, solar lentigo, seborrheic keratosis
- malignant: pigmented BCC

Management
- excisional biopsy preferable, otherwise incisional biopsy
- remove full depth of dermis and extend beyond edges of lesion only after histologic diagnosis
- beware of lesions that regress – tumour is usually deeper than anticipated
- high dose IFN for stage II (regional), chemotherapy (cis-platinum, BCG) and high dose IFN for stage III (distant) disease
- newer chemotherapeutic, gene therapies, and vaccines starting to be used in metastatic melanoma
- radiotherapy may be used as adjunctive treatment

a = no ulceration; b = ulceration
Other Cutaneous Cancers

CUTANEOUS T-CELL LYMPHOMA

Clinical Feature
- **Mycosis fungoides** (limited superficial type)
  - characterized by erythematous patches/plaques/nodules/tumours, which may be pruritic and poikilodermic (atrophy, telangiectasia, hyperpigmentation, hypopigmentation)
  - common sites include: trunk, buttocks, proximal limbs
  - mildly symptomatic, usually excellent prognosis for early disease
- **Sézary syndrome** (widespread systemic type)
  - rare variant characterized by erythroderma, lymphadenopathy, WBC >20 x 10⁹/L with Sézary cells
  - can be considered to have evolved from MF (not initially meeting diagnostic criteria), but more commonly arises de novo
  - associated with intense pruritus, alopecia, palmoplantar hyperkeratosis, and systemic symptoms (fatigue, fever)
  - often fatal

Pathophysiology
- clonal proliferation of skin-homing CD4 T-cells

Epidemiology
- >50 yr old, M:F 2:1

Differential Diagnosis
- tinea corporis, nummular dermatitis, psoriasis, DLE, Bowen's disease, adult T-Cell leukemia-lymphoma (ATL)

Investigations
- skin biopsy (histology, "lymphocyte antigen cell" markers, TcR gene arrangement)
- blood smear looking for Sézary cells or flow cytometry (e.g. CD4:CD8 >10 is Sézary)
- imaging (for systemic involvement)

Management
- **Mycosis fungoides**
  - depends on stage of disease
  - topical steroids and/or PUVA, NB-UVB (311-313 nm)
- **Sézary syndrome**
  - oral retinoids and IFN
  - extracorporeal photopheresis
  - may need radiotherapy for total skin electron beam radiation
  - may maintain on UV therapy
  - other chemotherapy agents

Diseases of Hair Density

Hair Growth
- hair grows in a cyclic pattern that is defined in 3 stages (most scalp hairs are in anagen phase)
  1. growth stage = anagen phase
  2. transitional stage = catagen stage
  3. resting stage = telogen phase
- total duration of the growth stage reflects the type and location of hair: eyebrow, eyelash, and axillary hairs have a short growth stage in relation to the resting stage
- growth of the hair follicles is also based on the hormonal response to testosterone and DHT; this response is genetically controlled

Non-Scarring (Non-Cicatricial) Alopecia

ANDROGENETIC ALOPECIA

Clinical Feature
- male- or female-pattern alopecia
  - males: fronto-temporal areas progressing to vertex, entire scalp may be bald
  - females: widening of central part, "Christmas tree" pattern

Pathophysiology
- action of dihydrotestosterone (DHT) on hair follicles

Epidemiology
- males: early 20s-30s
- females: 40s-50s
Management
- minoxidil (Rogaine®) solution or foam to reduce rate of loss/partial restoration
- females: spironolactone (anti-androgenic effects), cyproterone acetate (Diane-35®)
- males: finasteride (Propecia®) (5-α-reductase inhibitor) 1 mg/d
- hair transplant

TELOGEN EFFLUVIUM

Clinical Feature
- uniform decrease in hair density secondary to hairs leaving the growth (anagen) stage and entering the resting (telogen) stage of the cycle

Pathophysiology
- variety of precipitating factors (i.e. post-partum, psychological stress, major illness)
- hair loss typically occurs 2-4 mo after exposure to precipitant
- regrowth occurs within a few months but may not be complete

ANAGEN EFFLUVIUM

Clinical Feature
- hair loss due to insult of hair follicle impairing its mitotic activity (growth stage)

Pathophysiology
- precipitated by chemotherapeutic agents (most common), other meds (bismuth, levodopa, colchicine, cyclosporine), exposure to chemicals (thallium, boron, arsenic)
- dose-dependent effect
- hair loss 7-14 d after single pulse of chemotherapy; most clinically apparent after 1-2 mo
- reversible effect; follicles resume normal mitotic activity few weeks after agent stopped

ALOPECIA AREATA

Clinical Feature
- autoimmune disorder characterized by patches of complete hair loss often localized to scalp, but can affect eyebrows, beard, eyelashes, etc.
- may be associated with dystrophic nail changes – fine stippling, pitting
- “exclamation mark” pattern (hairs fractured and have tapered shafts, i.e. looks like “!”)
- may be associated with pernicious anemia, vitiligo, thyroid disease, Addison’s disease
- spontaneous regrowth may occur within months of first attack (worse prognosis if young at age of onset and extensive loss)
- frequent recurrence often precipitated by emotional distress
- alopecia totalis: complete loss of hair on scalp
- alopecia universalis: complete loss of scalp hair, eyelashes, eyebrows, and body hair

Management
- excellent prognosis for localized disease
- topical corticosteroids and intralesional triamcinolone acetonide (corticosteroids) can be used for isolated patches
- systemic immunosuppressants for refractory or extensive disease
- immunomodulatory (diphenycpron, anthralin)

OTHER
- trichotillomania: impulse-control disorder characterized by compulsive hair pulling with irregular patches of hair loss, and with remaining hairs broken at varying lengths
- traumatic (e.g. tight “corn-row” braiding of hair, wearing tight pony tails, tight tying of turbans)

Scarring (Cicatricial) Alopecia

Clinical Feature
- irreversible loss of hair follicles with fibrosis

Etiology
- physical: radiation, burns
- infections: fungal, bacterial, TB, leprosy, viral (HSV)
- primary inflammatory – subdivided into lymphocytic, neutrophilic, and mixed
  - lymphocytic:
    - lichen planus (lichen planopilaris) – white scale around hair follicles, up to 50% have lichen planus at other body sites
    - DLE (note that SLE can cause an alopecia unrelated to DLE lesions which are non-scarring)
  - central centrifugal cicatricial alopecia (CCCA): seen in up to 40% of black women, starting at central scalp; one of most commonly diagnosed scarring alopecias, may be associated with hair care practices in this population
Dermatology

Investigations
- biopsy from active border

Management
- infections: treat underlying infection
- inflammatory: topical/intralesional steroids, anti-inflammatory antibiotics, antimalarials

Miscellaneous Lesions

Angioedema and Urticaria

Angioedema
• deeper swelling of the skin involving subcutaneous tissues; often involves the eyes, lips, and tongue
• may or may not accompany urticaria
• hereditary or acquired forms
• hereditary angioedema (does not occur with urticaria)
  • onset in childhood; 80% have positive family history
  • recurrent attacks; 25% die from laryngeal edema
  • triggers: minor trauma, emotional upset, temperature changes
• types of acquired angioedema
  • acute allergic angioedema (allergens include food, drugs, contrast media, insect venom, latex)
  • non-allergic drug reaction (drugs include ACEI)
  • acquired C1 inhibitor deficiency
• treatment
  • prophylaxis with danazol or stanozolol for hereditary angioedema
  • epinephrine pen to temporize until patient reaches hospital in acute attack

Urticaria
• also known as “hives”
• transient, red, pruritic well-demarcated wheals
• each individual lesion lasts less than 24 h
• second most common type of drug reaction
• results from release of histamine from mast cells in dermis
• can also result after physical contact with allergen

</tbody>
</table>

Urticarial Vasculitis
Individual lesions last >24 h
• Often painful, less likely pruritic, heals with bruise type lesions
• Requires biopsy

Wheal
• Typically erythematous flat-topped, palpable lesions varying in size with circumscribed dermal edema
• Individual lesion lasts <24 h
• Associated with mast cell release of histamine
• May be pruritic

Mastocytosis (Urticaria Pigmentosa)
Rare disease due to excessive infiltration of the skin by mast cells. It manifests as many reddish-brown elevated plaques and macules. Friction to a lesion produces a wheal surrounded by intense erythema (Darier’s sign), due to mast cell degranulation; this occurs within minutes

DDx for Urticaria
DAM HIVES
Drugs and foods
Allergic
Malignancy
Hereditary
Infection
Vasculitis
Emotions
Stings

Approach to Urticaria
• Thorough Hx and P/E
• Acute: no immediate investigations needed; consider referral for allergy testing
• Chronic: further investigations required: CBC and differential, urinalysis, ESR, TSH, LFTs to help identify underlying cause
• Vasculitic: biopsy of lesion and referral to dermatology
Erythema Nodosum

Clinical Feature
- acute or chronic inflammation of subcutaneous fat (panniculitis)
- round, red, tender, poorly demarcated nodules
- sites: asymmetrically arranged on extensor lower legs (typically shins), knees, arms
- associated with arthralgia, fever, malaise

Etiology
- 40% are idiopathic
- drugs: sulfonamides, OCPs (also pregnancy), analgesics, trans retinoic acid
- infections: GAS, TB, histoplasmosis, Yersinia
- inflammation: sarcoidosis, Crohn’s > UC
- malignancy: acute leukemia, Hodgkin’s lymphoma

Epidemiology
- 15-30 yr old, F:M 3:1
- lesions last for days and spontaneously resolve in 6 wk

Investigations
- CXR (to rule out chest infection and sarcoidosis)
- throat culture, ASO titre, PPD skin test

Management
- symptomatic: bed rest, compressive bandages, wet dressings
- NSAIDs, intralesional steroids
- treat underlying cause

Pruritus

Clinical Feature
- a sensation provoking a desire to scratch, with or without skin lesions
- lesions may arise from the underlying disease, or from excoriation causing crusts, lichenified plaques, or wheals

Etiology
- dermatologic – generalized
  - atopic dermatitis (“winter itch” due to dry skin)
  - pruritus of senescent skin (may not have dry skin, any time of year)
  - infestations: scabies, lice
  - drug eruptions: ASA, antidepressants, opiates
  - psychogenic states
- dermatologic – local
  - atopic and contact dermatitis, lichen planus, urticaria, insect bites, dermatitis herpetiformis
  - infection: varicella, candidiasis
  - lichen simplex chronicus
  - prurigo nodularis
- systemic disease – usually generalized
  - hepatic: obstructive biliary disease, cholestatic liver disease of pregnancy
  - renal: chronic renal failure, uremia secondary to hemodialysis
  - hematologic: Hodgkin’s lymphoma, multiple myeloma, leukemia, polycythemia vera, hemochromatosis, Fe deficiency anemia, cutaneous T-cell lymphoma
  - neoplastic: lung, breast, gastric (internal solid tumours), non-Hodgkin’s lymphoma
  - endocrine: carcinoid, DM, hypothyroid/thyrotoxicosis
  - infectious: HIV, trichinosis, echinococcosis, hepatitis C
  - psychiatric: depression, psychosis
  - neurologic: post-herpetic neuralgia, multiple sclerosis

Investigations
- blood work: CBC, ESR, Cr/BUN, LFT, TSH, fasting blood sugar, stool culture, and serology for parasites

Management
- treat underlying cause
- cool water compresses to relieve pruritus
- bath oil and emollient ointment (especially if xerosis is present)
- topical corticosteroid and antipruritics (e.g. menthol, camphor, phenol, mirtazapine, capsaicin)
- systemic antihistamines: H1 blockers are most effective, most useful for urticaria
- phototherapy with UVB or PUVA
- doxepin, amitriptyline
- immunosuppressive agents if severe: steroids and steroid-sparing

DDx of Erythema Nodosum
- NO cause (idiopathic) in 40%
- Drugs (sulfonamides, OCP, etc.)
- Other infections (GAS+)
- Sarcoidosis
- UC and Crohn’s
- Malignancy (leukemia, Hodgkin’s lymphoma)
- Many Infections

DDx of Pruritus
- Scabies
- Cholestasis
- Renal
- Autoimmune
- Tumours
- Crazies (psychiatric)
- Hematology (polycythemia, lymphoma)
- Endocrine (thyroid, parathyroid, Fe)
- Drugs, Dry skin

Consider biopsy of any nonhealing wound to rule out cancer
Wounds and Ulcers

- see Plastic Surgery, PL8, PL16

**Sunburn (Solar Erythema)**

- erythema 2-6 h post UV exposure often associated with edema, pain and blistering with subsequent desquamation of the dermis, and hyperpigmentation
- chronic UVA and UVB exposure leads to photoaging, immunosuppression, photocarcinogenesis
- prevention: avoid peak UVR (10 am-4 pm), wear appropriate clothing, wide-brimmed hat, sunglasses, and broad-spectrum sunscreen
- clothing with UV protection expressed as UV protection factor (UPF) is analogous to SPF of sunscreen

**Sunscreens and Preventative Therapy**

- under ideal conditions an SPF of 10 means that a person who normally burns in 20 min will burn in 200 min following the application of the sunscreen
- topical chemical: absorbs UV light
  - requires application at least 15-30 min prior to exposure, should be reapplied every 2 h (more often if sweating, swimming)
  - UVB absorbers: PABA, salicylates, cinnamates, benzylidene camphor derivatives
  - UVA absorbers: benzophenones, anthranilates, dibenzoylmethanes, benzylidene camphor derivatives
- topical physical: reflects and scatters UV light
  - titanium dioxide, zinc oxide, kaolin, talc, ferric chloride, and melanin
  - all are effective against the UVA and UVB spectrum
  - less risk of sensitization than chemical sunscreens and waterproof, but may cause folliculitis or miliaria
- some sunscreen ingredients may cause contact or photocontact allergic reactions, but are uncommon

**Management**

- sunburn: if significant blistering present, consider treatment in hospital; otherwise, symptomatic treatment (cool wet compresses, oral anti-inflammatory, topical corticosteroids)
- antioxidants, both oral and topical are being studied for their abilities to protect the skin; topical agents are limited by their ability to penetrate the skin

**Topical Steroids**

**Table 25. Potency Ranking of Topical Steroids**

<table>
<thead>
<tr>
<th>Relative Potency</th>
<th>Relative Strength</th>
<th>Generic Names</th>
<th>Trade Names</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Weak</td>
<td>x1</td>
<td>hydrocortisone – 2.5% (1% available over-the-counter)</td>
<td>Emo Cort®</td>
<td>Intertriginous areas, children, face, thin skin</td>
</tr>
<tr>
<td>Moderate</td>
<td>x3</td>
<td>hydrocortisone 17-valerate – 0.2% desonide mometasone furoate</td>
<td>Westcort®</td>
<td>Arm, leg, trunk</td>
</tr>
<tr>

<tr>
<td>V</td>
<td>Brown</td>
<td>Rarely burns, dark tan</td>
</tr>
<tr>
<td>VI</td>
<td>Dark brown</td>
<td>Never burns, dark tan or black</td>
</tr>
</tbody>
</table>

**UV Radiation**

**UVA (320-400 nm): Aging**
- Penetrates skin more effectively than UVB or UVC
- Responsible for tanning, burning, wrinkling, photoallergy, and premature skin aging
- Penetrates clouds, glass and is reflected off water, snow, and cement

**UVB (290-320 nm): Burning**
- Absorbed by the outer dermis
- Is mainly responsible for burning and premature skin aging
- Primarily responsible for BCC, SCC
- Does not penetrate glass and is substantially absorbed by ozone

**UVC (200-290 nm)**
- Is filtered by ozone layer

**Body Site:**

<table>
<thead>
<tr>
<th>Relative Percutaneous Absorption</th>

<tr>
<td>Scrotum</td>
</tr>
</tbody>
</table>

Calculation of strength of steroid compared to hydrocortisone on forearm: relative strength of steroid x relative percutaneous absorption

**Side Effects of Topical Steroids**

- Local: atrophy, perioral dermatitis, steroid acne, rosacea, contact dermatitis, tachyphylaxis (tolerance), telangiectasia, striae, hypertrichosis, hypopigmentation
- Systemic: suppression of HPA axis
Dermatologic Therapies

### Table 26. Common Topical Therapies

<table>
<thead>
<tr>
<th>Drug Name</th>
<th>Dosing Schedule</th>
<th>Indications</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Calcipotriol (Dovonex&lt;sup&gt;®&lt;/sup&gt;)</td>
<td>0.005% cream, ointment, scalp solution, apply bid for maintenance therapy apply OD</td>
<td>Psoriasis</td>
<td>Burning, itching, skin irritation, worsening of psoriasis Avoid face, mucous membranes, eyes; wash hands after application Maximum weekly dosage of cream by age: 2-5 yr – 25 g/wk 6-10 yr – 50 g/wk 11-14 yr – 75 g/wk &gt;14 yr – 100 g/wk Inactivated by light (do not apply before phototherapy)</td>
</tr>
<tr>
<td>Imiquimod (Aldara&lt;sup&gt;®&lt;/sup&gt;)</td>
<td>5% cream applied 3x/wk Apply at bedtime, leave on 6-10 h, then wash off with mild soap and water Max duration 16 wk</td>
<td>Genital warts</td>
<td>Avoid natural/artificial UV exposure Local skin and application site reactions Erythema, ulceration, edema, flu-like symptoms Works best for warts on mucosal surfaces May induce inflammation and erosion</td>
</tr>
<tr>
<td>Permethrin (Kwellada® P Lotion and Nix® Dermal Cream)</td>
<td>1% or 5% cream, applied once overnight to all skin areas from neck down, repeated one week later</td>
<td>Scabies (Kwellada-P Lotion, Nix® Dermal Cream) Pediculosis (Kwellada-P Crème Rinse®, Nix Crème Rinse®)</td>
<td>Do not use in children &lt;2 yr Hypersensitivity to drug, or known sensitivity to chrysanthemums Local reactions (resolve rapidly); including burning, pruritus Low toxicity, excellent results Consider second application after 7 d</td>
</tr>
<tr>
<td>Pimecrolimus (Elidel&lt;sup&gt;®&lt;/sup&gt;)</td>
<td>1% cream bid Use for as long as lesions persist and discontinue upon resolution of symptoms</td>
<td>AD (mild to moderate)</td>
<td>Burning Lacks adverse effects of steroids May be used on all skin surfaces including head, neck, and intertriginous areas Expensive</td>
</tr>
<tr>
<td>Tacrolimus Topical (Protopic&lt;sup&gt;®&lt;/sup&gt;)</td>
<td>0.03% (children) or 0.1% (adults) ointment bid Continue for duration of disease PLUS 1 wk after clearing</td>
<td>AD (mild to moderate)</td>
<td>Burning Lacks adverse effects of steroids May be used on all skin surfaces including head, neck, and intertriginous areas Expensive</td>
</tr>
</tbody>
</table>

### Table 27. Common Oral Therapies

<table>
<thead>
<tr>
<th>Drug Name</th>
<th>Dosing Schedule</th>
<th>Indications</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Acitretin (Soriatane&lt;sup&gt;®&lt;/sup&gt;)</td>
<td>25-50 mg PO OD; maximum 75 mg/d</td>
<td>Severe psoriasis Other disorders of hyperkeratinization (ichthyosis, Darier’s disease)</td>
<td>Monitoring strategies Monitor lipids, LFTs at baseline and q1-2wk until stable Contraindications Women of childbearing potential unless strict contraceptive requirements are met Drug interactions Other systemic retinoids, methotrexate, tetracyclines, certain contraceptives May be combined with PUVA phototherapy (known as re-PUVA)</td>
</tr>
<tr>
<td>Antivirals</td>
<td>famiciclovir (Famvir&lt;sup&gt;®&lt;/sup&gt;) 250 mg PO bid x 7-10 d (for 1st episode of genital herpes) 125 mg PO bid x 5 d (for recurrent genital herpes)</td>
<td>Chickenpox Herpes zoster Genital herpes</td>
<td>Side effects Headache, nausea, diarrhea, abdominal pain Reduce dose if impaired renal function</td>
</tr>
<tr>
<td></td>
<td>valacyclovir (Valtrex&lt;sup&gt;®&lt;/sup&gt;) 1000 mg PO bid x 7-10 d (for 1st episode of genital herpes) 500 mg PO bid x 5 d (for recurrent genital herpes)</td>
<td>Acute and prophylactic to reduce transmission in infected patients Herpes labialis</td>
<td>Side effects Dizziness, depression, abdominal pain Reduce dose if impaired renal function Drug interactions cimetidine</td>
</tr>
<tr>
<td>Cyclosporine (Neoral&lt;sup&gt;®&lt;/sup&gt;)</td>
<td>2.5-4 mg/kg/d PO divided bid Max 4 mg/kg/d After 4 wk may increase by 0.5 mg/kg/d q2wk Concomitant dose of magnesium may protect the kidneys</td>
<td>Psoriasis May also be effective in: Lichen planus EM Recalcitrant urticaria Recalcitrant AD</td>
<td>Monitoring strategies Blood pressure, renal function Contraindications Abnormal renal function, uncontrolled hypertension, malignancy (except NMSC), uncontrolled infection, immunodeficiency (excluding autoimmune disease), hypersensitivity to drug Long-term effects preclude use of cyclosporine for &gt;2 yr; discontinue earlier if possible May consider rotating therapy with other drugs to minimize adverse effects of each drug</td>
</tr>
<tr>
<td>Dapsone</td>
<td>50-100-150 mg PO OD tapering to 25-50 mg PO OD to as low as 50 mg 2x/wk</td>
<td>Dermatitis herpetiformis, neutrophilic dermatoses</td>
<td>Monitoring strategies Obtain G6PD levels before initiating; in the initial 2 wk obtain methemoglobin levels and follow the blood counts carefully for the first few months Side effects Neuropathy Hemolysis (Vitamin C and E supplementation can help prevent this) Drug interactions Substrate of CYP2C8&lt;sub&gt;9&lt;/sub&gt; (minor), 2C19 (minor), 2E1 (minor), 3A4 (major) Often a dramatic response within hours</td>
</tr>
<tr>
<td>Drug Name</td>
<td>Dosing Schedule</td>
<td>Indications</td>
<td>Comments</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------------</td>
<td>------------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Doxycycline</td>
<td>50 mg PO bid</td>
<td>Acne vulgaris, Rosacea, Bullous pemphigoid</td>
<td>Contraindications: Pregnancy, hepatic impairment, drug hypersensitivity, Taking acitretin, isotretinoin, or penicillin antibiotic, Oral typhoid vaccine</td>
</tr>
<tr>
<td>Isotretinoin</td>
<td>0.5-1 mg/kg/d given OD to achieve a total dose of 120 mg/kg (20-24 wk)</td>
<td>Severe nodular and/or inflammatory acne, Acne conglobata, Recalcitrant acne, Widespread comedonal acne</td>
<td>Monitoring strategies: Baseline lipid profile and LFTs before treatment, β-hCG, Contraindications: Teratogenic – in sexually active females, 2 forms of reliable contraception necessary, Generally regarded as unsafe in lactation, Side effects: Decreased night vision, decreased tolerance to contact lenses, dry mucous membranes, May transiently exacerbate acne, dry skin, Depression, myalgia, Drug interactions: Caution if used at the same time as tetracyclinefamily antibiotics – both may cause pseudotumour cerebri, Discontinue vitamin A supplements, Drug may be discontinued at 16-20 wk when nodule count has dropped by &gt;70%; a second course may be initiated after 2 mo prn, Refractory cases may require &gt;3 courses</td>
</tr>
<tr>
<td>Itraconazole</td>
<td>100-400 mg PO OD, depending on infection</td>
<td>Onychomycosis, Tinea corporis, cruris, versicolor, capitis</td>
<td>Contraindications: CHF, Side effects: Serious hepatotoxicity, Drug Interactions: Inhibits CYP3A4, Increases concentration of some drugs metabolized by this enzyme (i.e. statins, diabetic drugs), Give capsules with food, capsules must be swallowed whole</td>
</tr>
<tr>
<td>Ivermectin</td>
<td>200-250 µg/kg PO qweekly x 2</td>
<td>Psoriasis, AD, Lymphomatoid papulosis, May also be effective for: cutaneous sarcoidosis</td>
<td>Monitoring strategies: Baseline renal, liver, and hematological studies, Contraindications: Pregnancy, lactation, alcohol abuse, liver dysfunction, immunodeficiency syndrome, blood dyscrasias, hypersensitivity to drug, Restricted to severe, recalcitrant or disabling psoriasis not adequately responsive to other forms of therapy, May be combined with cyclosporine to allow lower doses of both drugs</td>
</tr>
<tr>
<td>Methotrexate</td>
<td>10-25 mg qwk, PO, IM, or IV Max: 30 mg/vwk To minimize side effects, administer with folic acid supplementation: 1-5 mg OD</td>
<td>Psoriasis, AD, Lymphomatoid papulosis, May also be effective for: cutaneous sarcoidosis</td>
<td>Monitoring strategies: Baseline renal, liver, and hematological studies, Contraindications: Pregnancy, lactation, alcohol abuse, liver dysfunction, immunodeficiency syndrome, blood dyscrasias, hypersensitivity to drug, Restricted to severe, recalcitrant or disabling psoriasis not adequately responsive to other forms of therapy, May be combined with cyclosporine to allow lower doses of both drugs</td>
</tr>
<tr>
<td>OCPs</td>
<td>1 pill PO OD</td>
<td>Hormonal acne (chin, jawline), Acne associated with polycystic ovarian syndrome or other endocrine abnormalities</td>
<td>All combined OCPs are helpful in acne but those listed on the left have undergone RCTs, Contraindications: Smoking, HTN, migraines with aura, pregnancy, Routine gynecological health maintenance should be up to date</td>
</tr>
<tr>
<td>Spironolactone</td>
<td>50-100 mg PO OD alone or with OCPs</td>
<td>Hormonal acne (chin, jawline), Acne with endocrine abnormality</td>
<td>Contraindications: Pregnancy, Side effects: Menstrual irregularities at higher doses if not on OCPs, Breast tenderness, mild diuresis common, Risk of hyperkalemia – counsel patients to reduce intake of potassium rich foods such as bananas</td>
</tr>
<tr>
<td>Terbinafine</td>
<td>250 mg PO OD x 2 wk</td>
<td>Onychomycosis, Tinea corporis, cruris, pedis, capitis</td>
<td>Contraindications: Pregnancy, chronic or active liver disease, Drug interactions: Potent inhibitor of CYP2D6; use with caution when also taking β-blockers, certain anti-arrhythmic agents, MAOI type B, and/or antipsychotics, Drug concentrates rapidly in skin, hair, and nails at levels associated with fungicidal activity</td>
</tr>
<tr>
<td>Tetracycline</td>
<td>250-500 mg PO bid to tid Taken 1 h before or 2 h after a meal</td>
<td>Acne vulgaris, Rosacea, Bullous pemphigoid</td>
<td>Contraindications: Severe renal or hepatic dysfunction</td>
</tr>

TIA transient ischemic attack
TSS toxic shock syndrome
U/A urinalysis
U/S ultrasound
U/A urinalysis
U/L urine toxicology screen
VBD venous blood gas
VfV venous thromboembolism
VTE venous thromboembolism

Patient Assessment/Management

1. Rapid Primary Survey

- Airway maintenance with C-spine control
- Breathing and ventilation
- Circulation (pulses, hemorrhage control)
- Disability (neurological status)
- Exposure (complete) and Environment (temperature control)
  - continually reassessed during secondary survey
  - changes in hemodynamic and/or neurological status necessitates a return to the primary survey
  - beginning with airway assessment
- IMPORTANT: Always watch for signs of shock while doing primary survey
- addressing the “ABCs” is the hallmark of the emergency department
  - in the setting of cardiac arrest, the approach changes to “the CABS”: chest compressions, airway, and breathing
  - CAB can also be applied in massive trauma situations, in the setting of massive blood loss to treat hypovolemic shock

A. AIRWAY

  - first priority is to secure airway
  - assume a cervical injury in every trauma patient and immobilize with collar
  - assess ability to breathe and speak
  - can change rapidly, therefore reassess frequently
  - assess for facial fractures/edema/burns (impending airway collapse)

Airway Management

- anatomic optimization to allow for oxygenation and ventilation

1. Basic Airway Management

  - protect the C-spine
  - head-tilt (if C-spine injury not suspected) or jaw thrust to open the airway
  - sweep and suction to clear mouth of foreign material

2. Temporizing Measures

  - nasopharyngeal airway (if gag reflex present, i.e. conscious)
  - oropharyngeal airway (if gag reflex absent, i.e. unconscious)
  - “rescue” airway devices (e.g. laryngeal mask airway, Combitube®)
  - transtracheal jet ventilation through cricothyroid membrane (last resort)

3. Definitive Airway Management

  - ETT intubation with in-line stabilization of C-spine
    - orotracheal ± RSI preferred
    - nasotracheal may be better tolerated in conscious patient
    - relatively contraindicated with basal skull fracture
    - does not provide 100% protection against aspiration
    - surgical airway (if unable to intubate using oral/nasal route and unable to ventilate)
    - cricothyroidotomy

Contraindications to Intubation

- supraglottic/glottic pathology that would preclude successful intubation
B. BREATHING

- **Look**
  - mental status (anxiety, agitation, decreased LOC), colour, chest movement (bilateral vs. asymmetrical), respiratory rate/effort, nasal / larynges

- **Listen**
  - auscultate for signs of obstruction (e.g. stridor), breath sounds, symmetry of air entry, air escaping

- **Feel**
  - tracheal shift, chest wall for crepitus, flail segments, sucking chest wounds, subcutaneous emphysema

**Breathing Assessment**
- objective measures of respiratory function: rate, oximetry, ABG, A-a gradient

**Management of Breathing**
- nasal prongs → simple face mask → non-rebreather mask → CPAP/BiPAP (in order of increasing FiO2)
- Bag-Valve mask and CPAP to supplement inadequate ventilation

C. CIRCULATION

**Definition of Shock**
- inadequate organ and tissue perfusion with oxygenated blood (brain, kidney, extremities)

**Table 1. Major Types of Shock**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

**Clinical Evaluation**
- early: tachypnea, tachycardia, narrow pulse pressure, reduced capillary refill, cool extremities, and reduced central venous pressure
- late: hypotension and altered mental status, reduced urine output

**Table 2. Estimation of Degree of Hemorrhagic Shock**

**Indications for Intubation (5 P’s)**
- Patent airway
- Protects against aspiration
- Positive pressure ventilation
- Pulmonary toilet (suction)
- Pharmacologic administration during hemodynamic instability

**Rescue Techniques in Intubation**
- Bougie (used like a guidewire)
- Glidescope®
- Lighted stylet (uses light through skin to determine if ETT in correct place)
- Fiberoptic intubation – (uses fiberoptic cable for indirect visualization)

**O2 Delivery Methods**

</tbody>
</table>

**Causes of Shock**

- SHOCKED
  - Septic, spinal/neurogenic
  - Hemorrhagic
  - Obstructive (e.g. tension pneumothorax, cardiac tamponade, PE)
  - Cardiogenic (e.g. blunt myocardial injury, dysrhythmia, MI)
  - Anaphylactic
  - Endocrine (e.g. Addison’s, myxedema, coma)
  - Drugs

**Noisy breathing is obstructed breathing until proven otherwise**

**Shock in a trauma patient is hemorrhagic until proven otherwise**
Management of Hemorrhagic Shock
- clear airway and assess breathing either first or simultaneously
- apply direct pressure on external wounds while elevating extremities. Do not remove impaled objects in the emergency room setting as they may tamponade bleeds
- start TWO LARGE BORE (14-16G) IVs in the brachial/cephalic vein of each arm
- run 1-2 L bolus of IV Normal Saline/Ringer’s Lactate (warmed, if possible)
- if continual bleeding or no response to crystalloids, consider pRBC transfusion, ideally crossmatched. If crossmatched blood is unavailable, consider O- for women of childbearing age and O+ for men. Use FFP, platelets or tranexamic acid in early bleeding
- consider common sites of internal bleeding (abdomen, chest, pelvis, long bones) where surgical intervention may be necessary

D. DISABILITY
- assess LOC using GCS
- pupils
  - assess equality, size, symmetry, reactivity to light
  - unequal or sluggish suggests local eye problem or lateralizing CNS lesion
  - relative afferent pupillary defect (swinging light test) – optic nerve damage
  - extraocular movements and nystagmus
  - fundoscopy (papilledema, hemorrhages)
  - reactive pupils + decreased LOC: metabolic or structural cause
  - non-reactive pupils + decreased LOC: structural cause (especially if asymmetric)

Glasgow Coma Scale
- for use in trauma patients with decreased LOC; good indicator of severity of injury and neurosurgical prognosis
- most useful if repeated; change in GCS with time is more relevant than the absolute number
- less meaningful for metabolic coma
- patient with deteriorating GCS needs immediate attention
- prognosis based on best post-resuscitation GCS
- reported as a 3 part score: Eyes + Verbal + Motor = Total
- if patient intubated, GCS score reported out of 10 + T (T = tubed, i.e. no verbal component)

Table 3. Glasgow Coma Scale

13-15 = mild injury, 9-12 = moderate injury, ≤8 = severe injury

E. EXPOSURE/ENVIRONMENT
- expose patient completely and assess entire body for injury; log roll to examine back
- DRE
- keep patient warm with a blanket ± radiant heaters; avoid hypothermia
- warm IV fluids/blood
- keep providers safe (contamination, combative patient)

2. Resuscitation
- done concurrently with primary survey
- attend to ABCs
- manage life-threatening problems as they are identified
- vital signs q5-15 min
- ECG, BP, and O2 monitors
- Foley catheter and NG tube if indicated
- tests and investigations: CBC, electrolytes, BUN, Cr, glucose, amylase, INR/PTT, β-hCG, toxicology screen, cross and type

3. Secondary Survey

- done after primary survey once patient is hemodynamically and neurologically stabilized
- identifies major injuries or areas of concern
- full physical exam and x-rays (C-spine, chest, and pelvis – required in blunt trauma, consider T-spine and L-spine if indicated)

HISTORY

- “SAMPLE”: Signs and symptoms, Allergies, Medications, Past medical history, Last meal, Events related to injury

   - bladder (B)
   - free fluid (F)
PHYSICAL EXAM

Head and Neck
  • palpation of facial bones, scalp

Chest
  • inspect for midline trachea and flail segment ≥2 rib fractures in ≥2 places; if present look for associated
    hemothorax, pneumothorax, and contusions
  • auscultate lung fields
  • palpate for subcutaneous emphysema

Abdomen
  • assess for peritonitis, abdominal distention, and evidence of intra-abdominal bleeding
  • DRE for GI bleed, high riding prostate, and anal tone

Musculoskeletal
  • examine all extremities for swelling, deformity, contusions, tenderness, ROM
  • check for pulses (using Doppler probe) and sensation in all injured limbs
  • log roll and palpate thoracic and lumbar spines
  • palpate iliac crests and pubic symphysis and assess pelvic stability (lateral, AP, vertical)

Neurological
  • GCS
  • full cranial nerve exam
  • alterations of rate and rhythm of breathing are signs of structural or metabolic abnormalities with
    progressive deterioration in breathing indicating a failing CNS
  • assess spinal cord integrity
  • conscious patient: assess distal sensation and motor function
  • unconscious patient: response to painful or noxious stimulus applied to extremities

INITIAL IMAGING
  • non-contrast CT head/face/C-spine (rule out fractures and bleeds)
  • chest x-ray
  • FAST (see Figure 2) or CT abdomen/pelvis (if stable)
  • pelvis x-ray

Ethical Considerations

Consent to Treatment: Adults
  • see Ethical, Legal, and Organizational Medicine, ELOM7
  • Emergency Rule: consent is not needed when a patient is at imminent risk from a serious injury AND
    obtaining consent is either: a) not possible, OR b) would increase risk to the patient
    • assumes that most people would want to be saved in an emergency
  • any capable and informed patient can refuse treatment or part of treatment, even if it is life-saving
  • exceptions to the Emergency Rule – treatment cannot be initiated if:
    • a competent patient has previously refused the same or similar treatment and there is no evidence to
      suggest the patient’s wishes have changed
    • an advanced directive is available (e.g. do not resuscitate order)
    • NOTE: refusal of help in a suicide situation is NOT an exception; care must be given
  • if in doubt, initiate treatment
  • care can be withdrawn if necessary at a later time or if wishes are clarified by family

Consent to Treatment: Children
  • treat immediately if patient is at imminent risk
  • parents/guardians have the right to make treatment decisions
  • if parents refuse treatment that is life-saving or will potentially alter the child’s quality of life, CAS must
    be contacted – consent of CAS is needed to treat

Other Issues of Consent
  • need consent for HIV testing, as well as for administration of blood products
  • however, if delay in substitute consent for blood transfusions puts patient at risk, transfusions can be
    given

Duty to Report
  • law may vary depending on province and/or state
  • examples: gunshot wounds, suspected child abuse, various communicable diseases, medical
    unsuitability to drive, risk of substantial harm to others
Traumatology

- epidemiology
  - leading cause of death in patients <45 yr
  - 4th highest cause of death in North America
  - causes more deaths in children/adolescents than all diseases combined
- trimodal distribution of death
  - minutes: death usually at the scene from lethal injuries
  - early: death within 4-6 h – “golden hour” (decreased mortality with trauma care)
  - days-weeks: death from multiple organ dysfunction, sepsis, VTE, etc.
- injuries fall into two categories
  - blunt (most common): MVC, pedestrian-automobile impact, motorcycle collision, fall, assault, sports
  - penetrating (increasing in incidence): gunshot wound, stabbing, impalement

Considerations for Traumatic Injury

- important to know the mechanism of injury to anticipate traumatic injuries
- always look for an underlying cause (alcohol, medications, illicit substances, seizure, suicide attempt, medical problem)
- always inquire about HI, loss of consciousness, amnesia, vomiting, headache, and seizure activity

Table 5. Mechanisms and Considerations of Traumatic Injuries

<table>
<thead>
<tr>
<th>Mechanism of Injury</th>
<th>Special Considerations</th>
<th>Associated Injuries</th>
</tr>
</thead>
<tbody>
<tr>
<td>MVC</td>
<td>Vehicle(s) involved: weight, size, speed, damage Location of patient in vehicle Use and type of seatbelt Ejection of patient from vehicle Entrapment of patient under vehicle Airbag deployment Helmet use in motorcycle collision</td>
<td>Head-on collision: head/facial, thoracic (aortic), lower extremity Lateral/T-bone collision: head, C-spine, thoracic, abdominal, pelvic, and lower extremity Rear-end collision: hyper-extension of C-spine (whiplash injury) Rollover</td>
</tr>
<tr>
<td>Pedestrian-Automobile Impact</td>
<td>High morbidity and mortality Vehicle speed is an important factor Site of impact on car</td>
<td>Children at increased risk of being run over (multisystem injuries) Adults tend to be struck in lower legs (lower extremity injuries), impacted against car (truncal injuries), and thrown to ground (HI)</td>
</tr>
<tr>
<td>Falls</td>
<td>1 storey = 12 ft = 3.6 m Distance of fall: 50% mortality at 4 storeys and 95% mortality at 7 storeys Landing position (vertical vs. horizontal)</td>
<td>Vertical: lower extremity, pelvic, and spine fractures; HI Horizontal: facial, upper extremity, and rib fractures; abdominal, thoracic, and HI</td>
</tr>
</tbody>
</table>

Head Trauma

- see Neurosurgery, NS30
- 60% of MVC-related deaths are due to HI

Specific Injuries

- fractures
  - Dx: non-contrast head CT and physical exam
  - A. skull fractures
    - vault fractures
      - linear, non-depressed
      - most common
      - typically occur over temporal bone, in area of middle meningeal artery (commonest cause of epidural hematoma)
    - depressed
      - open (associated overlying scalp laceration and torn dura, skull fracture disrupting paranasal sinuses or middle ear) vs. closed
  - basal skull fractures
    - typically occur through floor of anterior cranial fossa (longitudinal more common than transverse)
    - generally a clinical diagnosis (poorly visualized on CT)
    - associated with battle signs or raccoon eyes
  - B. facial fractures (see Plastic Surgery, PL31)
    - neuronal injury
    - beware of open fracture or sinus fractures (risk of infection)
    - severe facial fractures may pose risk to airway from profuse bleeding
scalp laceration
- can be a source of significant bleeding
- achieve hemostasis, inspect and palpate for skull bone defects ± CT head (rule-out skull fracture)

neuronal injury
A. diffuse
- mild TBI = concussion
  - transient alteration in mental status that may involve loss of consciousness
  - hallmarks of concussion: confusion and amnesia, which may occur immediately after the trauma or minutes later
  - loss of consciousness (if present) must be less than 30 min, initial GCS must be between 13-15, and post-traumatic amnesia must be less than 24 h
- diffuse axonal injury
  - mild: coma 6-24 h, possibly lasting deficit
  - moderate: coma >24 h, little or no signs of brainstem dysfunction
  - severe: coma >24 h, frequent signs of brainstem dysfunction
B. focal injuries
- contusions
- intracranial hemorrhage (epidural, subdural, intracerebral)

ASSESSMENT OF BRAIN INJURY

History
- pre-hospital status
- mechanism of injury

Physical Exam
- assume C-spine injury until ruled out
- vital signs
  - shock (not likely due to isolated brain injury, except in infants)
  - Cushing's response to increasing ICP (bradycardia, HTN, irregular respirations)
- severity of injury determined by
  1. LOC
    - GCS ≤8 intubate, any change in score of 3 or more = serious injury
    - mild TBI = 13-15, moderate = 9-12, severe = 3-8
  2. pupils: size, anisocoria >1 mm (in patient with altered LOC), response to light
  3. lateralizing signs (motor/sensory)
    - may become subtler with increasing severity of injury
    - reassess frequently

Investigations
- labs: CBC, electrolytes, INR/PTT, glucose, toxicology screen
- CT scan head and neck (non-contrast) to exclude intracranial hemorrhage/hematoma
- C-spine imaging

Management
- goal in ED: reduce secondary injury by avoiding hypoxia, ischemia, decreased CPP, seizure
- general
  - ABCs
  - ensure oxygen delivery to brain through intubation and prevent hypercarbia
  - maintain BP (sBP >90)
- treat other injuries
- early neurosurgical consultation for acute and subsequent patient management
- seizure treatment/prophylaxis
  - benzodiazepines, phenytoin, phenobarbital
  - steroids are of no proven value
- treat suspected raised ICP, consider if HI with signs of increased ICP:
  - intubate
  - calm (sedate) if risk for high airway pressures or agitation
  - paralyze if agitated
  - hyperventilate (100% O2) to a pCO2 of 30-35 mmHg
  - elevate head of bed to 20°
  - adequate BP to ensure good cerebral perfusion
  - diurese with mannitol 1g/kg infused rapidly (contraindicated in shock/renal failure)

Disposition
- neurosurgical ICU admission for severe HI
- in hemodynamically unstable patient with other injuries, prioritize most life-threatening injuries and maintain cerebral perfusion
- for minor HI not requiring admission, provide 24 h HI protocol to competent caregiver, follow-up with neurology as even seemingly minor HI may cause lasting deficits

Warning Signs of Severe Head Injury
- GCS ≤8
- Deteriorating GCS
- Unequal pupils
- Lateralizing signs
N.B. Altered LOC is a hallmark of brain injury

Canadian CT Head Rule
Lancet 2001;357:1391-96
CT Head is only required for patients with minor HI with any one of the following
- High Risk (for neurological intervention)
  - GCS score ≤15 at 2 h after injury
  - Suspected open or depressed skull fracture
  - Any sign of basal skull fracture (hemotympanum, "raccoon" eyes, CSF otorrhoea/rhinorhena, Battle's sign)
  - Vomiting ≥2 episodes
  - Age ≥65 yr
- Medium Risk (for brain injury on CT)
  - Amnesia before impact >30 min (i.e. cannot recall events just before impact)
  - Dangerous mechanism (pedestrian struck by MVC, occupant ejected from motor vehicle, fall from height >3 ft or five stairs)
- Minor HI is defined as witnessed loss of consciousness, definite amnesia, or witnessed disorientation in a patient with a GCS score of 13-15.
N.B. Canadian CT Head Rule does not apply for non-trauma cases, for GCS<13, age <16, for patients on Coumadin® and/or having a bleeding disorder, or having an obvious open skull fracture.
Mild Traumatic Brain Injury

Epidemiology
- TBI results in 1.7 million deaths, hospitalizations, and ED visits each year (US)
- 75% are estimated to be mild TBI; remainder are moderate or severe (see Neurosurgery, NS31)
- highest rates in children 0-4 yr, adolescents 15-19 yr, and elderly >65 yr

Clinical Features
- somatic: headache, sleep disturbance, N/V, blurred vision
- cognitive dysfunction: attentional impairment, reduced processing speed, drowsiness, amnesia
- emotion and behaviour: impulsivity, irritability, depression
- severe concussion: may precipitate seizure, bradycardia, hypotension, sluggish pupils

Etiology
- falls, MVC, struck by an object, assault, sports

Investigations
- neurological exam
- concussion recognition tool (see thinkfirst.ca)
- imaging – CT as per Canadian CT Head Rules, or MRI if worsening symptoms despite normal CT

Treatment
- close observation and follow-up; for patients at risk of intracranial complications, give appropriate
  discharge instructions to patient and family; watch for changes to clinical features above, and if change,
  return to ED
- hospitalization with normal CT (GCS <15, seizures, bleeding diathesis), or with abnormal CT
- pharmacological management of pain, depression, headache
- follow Return to Play guidelines

Prognosis
- most recover with minimal treatment
  - athletes with previous concussion are at increased risk of cumulative brain injury
  - repeat TBI can lead to life-threatening cerebral edema or permanent impairment

Spine and Spinal Cord Trauma

- assume cord injury with significant falls (>12 ft), deceleration injuries, blunt trauma to head, neck, or
  back
- spinal immobilization (cervical collar, spine board during patient transport only) must be maintained
  until spinal injury has been ruled out (see Figure 3)
- vertebral injuries may be present without spinal cord injury; normal neurologic exam does not exclude
  spinal injury
- cord may be injured despite normal C-spine x-ray (spinal cord injury without radiologic abnormality)
- injuries can include: complete/incomplete transection, cord edema, spinal shock

History
- mechanism of injury, previous deficits, SAMPLE
- neck pain, paralysis/weakness, paresthesia

Physical Exam
- ABCs
- abdominal: ecchymosis, tenderness
- neurological: complete exam, including mental status
- spine: maintain neutral position, palpate C-spine; log roll, then palpate T-spine and L-spine, assess rectal tone
  - when palpating, assess for tenderness, muscle spasm, bony deformities, step-off, and spinous
    process malalignment
- extremities: check capillary refill, suspect thoracolumbar injury with calcaneal fractures

Investigations
- bloodwork: CBC, electrolytes, Cr, glucose, coagulation profile, cross and type, toxicology screen
- imaging
  - full C-spine x-ray series for trauma (AP, lateral, odontoid)
  - thoracolumbar x-rays
  - AP and lateral views
- Cauda Equina Syndrome can occur with any spinal cord injury below T10 vertebrae. Look for incontinence, anterior thigh pain, quadriiceps weakness, abnormal sacral sensation, decreased rectal tone, and variable reflexes
- Of the investigations, the lateral C-spine x-ray is the single most important film; 95% of radiologically visible abnormalities are found on this film
- Every Patient with One or More of the Following Signs or Symptoms should be Placed in a C-Spine Collar
  - Midline tenderness
  - Neurological symptoms or signs
  - Significant distracting injuries
  - NI
  - Intoxication
  - Dangerous mechanism
  - History of altered LOC

The Canadian C-Spine Rule vs. the NEXUS Low-Risk Criteria in Patients with Trauma
NEJM 2003;349:2510-18
Purpose: To compare the clinical performance of the Canadian C-Spine Rule (CCR) and the National Emergency X-Radiography Utilization Study (NEXUS) Low-Risk Criteria (NLC).

Study: Trauma patients (n=8283) in stable condition were prospectively evaluated by both CCR and NLC by 394 physicians before radiography. 2% of these patients had a C-spine injury.

Results: Compared to the NLC, the CCR was more sensitive (99.4 vs. 90.7%) and more specific (45.1 vs. 38.9%) after exclusion of indeterminate cases. The number of missed patients would be 1 for the CCR and 16 for the NLC. The ROM was not evaluated in some CCR cases likely because physicians were not comfortable with the procedure and this may slightly lower the sensitivity or specificity of the CCR in practice.

Summary: The CCR is superior to the NLC in alert and stable patients with trauma. The use of the CCR can result in lower radiography rates.
- indications
  - C-spine injury
  - unconscious patients (with appropriate mechanism of injury)
  - neurological symptoms or findings
  - deformities that are palpable when patient is log rolled
  - back pain
  - bilateral calcaneal fractures (due to fall from height)
  - concurrent burst fractures of the lumbar or thoracic spine in 10% (T11-L2)
  - consider CT (for subtle bony injuries), MRI (for soft tissue injuries) if appropriate

> Figure 3. Approach to clearing the C-spine

**Can Clear C-Spine if:**
- oriented to person, place, time, and event
- no evidence of intoxication
- no posterior midline cervical tenderness
- no focal neurological deficits
- no painful distracting injuries (e.g. long bone fracture)

**Management of Cord Injury**
- immobilize
- evaluate ABCs
- treat neurogenic shock (maintain sBP >100 mmHg)
- insert NG and Foley catheter
- complete imaging of spine and consult spine service if available
- continually reassess high cord injuries as edema can travel up cord
- if cervical cord lesion, watch for respiratory insufficiency
  - low cervical transection (C5-T1) produces abdominal breathing (phrenic innervation of diaphragm still intact but loss of innervation of intercostals and other accessory muscles of breathing)
  - high cervical cord injury (above C4) may require intubation and ventilation
- treatment: warm blanket, Trendelenburg position (occasionally), volume infusion, consider vasopressors

**Approach to C-Spine X-Rays**
- 3-view C-spine series is the screening modality of choice
  1. lateral C1-T1 ± swimmer’s view
  2. odontoid view (open mouth or oblique submental view)
  3. flexion/extension films

> Figure 4. Lines of contour on a lateral C-spine x-ray

- Prevertebral soft tissue swelling is only 49% sensitive for injury
3. AP view
- alignment of spinous processes in the midline
- spacing of spinous processes should be equal
- check vertebral bodies and facet dislocations

Table 6. Interpretation of Lateral View: The ABCS

</tr>
</tbody>
</table>

Sequelae of C-Spine Fractures
- see Neurosurgery, NS34
- acute phase of SCI
  - spinal shock: absence of all voluntary and reflex activity below level of injury
  - decreased reflexes, no sensation, flaccid paralysis below level of injury, lasting days to months
  - neurogenic shock: loss of vasomotor tone, SNS tone
    - watch for: hypotension (lacking SNS), bradycardia (unopposed PNS), poikilothermia (lacking SNS so no shunting of blood from extremities to core)
    - occurs within 30 min of SCI at level T6 or above, lasting up to 6 wk
    - provide airway support, fluids, atropine (for bradycardia), vasopressors for BP support
- chronic phase of SCI
  - autonomic dysreflexia: in patients with an SCI at level T6 or above
    - signs and symptoms: pounding headache, nasal congestion, feeling of apprehension or anxiety, visual changes, dangerously increased sBP and dBP
    - common triggers
      - GU causes: bladder distention, urinary tract infection, and kidney stones
      - GI causes: fecal impaction or bowel distension
    - treatment: monitoring and controlling BP, prior to addressing causative issue

Chest Trauma
- two types: those found and managed in 1st survey and those found and managed in 2nd survey

Table 7. Life-Threatening Chest Injuries Found in 1st Survey

<table>
<thead>
<tr>
<th>Physical Exam</th>
<th>Investigations</th>
<th>Management</th>

<tr>
<td>Airway Obstruction</td>
<td>Anxiety, stridor, hoarseness, altered mental status Apnea, cyanosis</td>
<td>Do not wait for ABG to intubate</td>
</tr>
</tbody>
</table>

Tension Pneumothorax
Clinical diagnosis
One-way valve causing accumulation of air in pleural space

| Respiratory distress, tachycardia, distended neck veins, cyanosis, asymmetry of chest wall motion Tracheal deviation away from pneumothorax Percussion hypo-resonance Unilateral absence of breath sounds | Non-radiographic diagnosis | Needle thoracostomy – large bore needle, 2nd ICS mid clavicular line, followed by chest tube in 5th ICS, anterior axillary line |

Trauma to the chest accounts for 50% of trauma deaths
80% of all chest injuries can be managed non-surgically with simple measures such as intubation, chest tubes, and pain control
Penetrating Neck Trauma
- includes all penetrating trauma to the three zones of the neck
- management: injuries deep to platysma require further evaluation by angiography, contrast CT, or surgery
- do not explore penetrating neck wounds except in the OR

Table 7. Life-Threatening Chest Injuries Found in 1° Survey (continued)

<tbody>
<tr>
<td>Pulmonary Contusion</td>
<td>Blunt trauma to chest Interstitial edema impairs compliance and gas exchange</td>
<td>CXR: areas of opacification of lung within 6 h of trauma Maintain adequate ventilation Monitor with ABG, pulse oximeter, and ECG Chest physiotherapy Positive pressure ventilation if severe</td>
</tr>
<tr>
<td>Ruptured Diaphragm</td>
<td>Blunt trauma to chest or abdomen (e.g. high lap belt in MVC)</td>
<td>CXR: abnormality of diaphragm/lower lung fields/NG tube placement CT scan and endoscopy: sometimes helpful for diagnosis Laparotomy for diaphragm repair and associated intra-abdominal injuries</td>
</tr>
<tr>
<td>Esophageal Injury</td>
<td>Usually penetrating trauma (pain out of proportion to degree of injury)</td>
<td>CXR: mediastinal air (not always) Esophagram (Gastrograffin®) Flexible esophagoscopy Early repair (within 24 h) improves outcome but all require repair</td>
</tr>
<tr>
<td>Aortic Tear</td>
<td>Sudden high speed deceleration (e.g. MVC, fall, airplane crash), complaints of chest pain, dyspnea, hoarseness (frequently absent) Decreased femoral pulses, differential arm BP (arch tear)</td>
<td>CXR, CT scan, transesophageal echo, aortography (gold standard) Thoracotomy (may treat other severe injuries first)</td>
</tr>
<tr>
<td>Blunt Myocardial Injury</td>
<td>Blunt trauma to chest (usually in setting of multi-system trauma and therefore difficult to diagnose) Physical exam: overlying injury e.g. fractures, chest wall contusion</td>
<td>ECG: dysrhythmias, ST changes Patients with a normal ECG and normal hemodynamics never get dysrhythmias O₂: Antidysrhythmic agents Analgesia</td>
</tr>
</tbody>
</table>

Other Potentially Life-Threatening Injuries Related to the Chest

Penetrating Neck Trauma
- includes all penetrating trauma to the three zones of the neck
- management: injuries deep to platysma require further evaluation by angiography, contrast CT, or surgery
- do not explore penetrating neck wounds except in the OR
**Abdominal Trauma**

- **two mechanisms**
  - blunt: usually causes solid organ injury (spleen = most common, liver = 2nd)
  - penetrating: usually causes hollow organ injury or liver injury (most common)

**BLUNT TRAUMA**

- results in two types of hemorrhage: intra-abdominal and retroperitoneal
- adopt high clinical suspicion of bleeding in multi-system trauma

**History**

- mechanism of injury, SAMPLE history

**Physical Exam**

- often unreliable in multi-system trauma, wide spectrum of presentations
  - slow blood loss not immediately apparent
  - tachycardia, tachypnea, oliguria, febrile, hypotension
  - other injuries may mask symptoms
  - serial examinations are required
- abdomen
  - inspect: contusions, abrasions, seat-belt sign, distention
  - auscultate: bruits, bowel sounds
  - palpate: tenderness, rebound tenderness, rigidity, guarding
  - DRE: rectal tone, blood, bone fragments, prostate location
  - placement of NG, Foley catheter should be considered part of the abdominal exam
  - other systems to assess: cardiovascular, respiratory (possibility of diaphragm rupture), genitourinary, pelvis, back/neurological

**Investigations**

- labs: CBC, electrolytes, coagulation, cross and type, glucose, Cr, CK, lipase, amylase, liver enzymes, ABG, blood EtOH, β-hCG, U/A, toxicology screen

<table>

<td>Chest (looking for free air under diaphragm, diaphragmatic hernia, air-fluid levels), pelvis, cervical, thoracic, lumbar spines</td>
<td>Soft tissue not well visualized</td>
</tr>
<tr>
<td>CT Scan</td>
<td>Most specific test</td>
<td>Radiation exposure 20x more than x-ray, Cannot use if hemodynamic instability</td>
</tr>
<tr>
<td>Diagnostic Peritoneal Lavage (rarely used)</td>
<td>Most sensitive test</td>
<td>Tests for intra-peritoneal bleed</td>
</tr>
<tr>
<td>Ultrasound: FAST</td>
<td>Identifies presence/absence of free fluid in peritoneal cavity</td>
<td>RAPID exam: less than 5 min</td>
</tr>
</tbody>
</table>
imaging must be done if:
- equivocal abdominal examination, altered sensorium, or distracting injuries (e.g. head trauma, spinal cord injury resulting in abdominal anesthesia)
- unexplained shock/hypotension
- patients have multiple traumas and must undergo general anesthesia for orthopedic, neurosurgical, or other injuries
- fractures of lower ribs, pelvis, spine
- positive FAST

Management
- general: ABCs, fluid resuscitation, and stabilization
- surgical: watchful waiting vs. laparotomy
- solid organ injuries: decision based on hemodynamic stability, not the specific injuries
- hemodynamically unstable or persistently high transfusion requirements: laparotomy
- hollow organ injuries: laparotomy
- even if low suspicion of injury: admit and observe for 24 h

PENETRATING TRAUMA
- high risk of gastrointestinal perforation and sepsis
- history: size of blade, calibre/distance from gun, route of entry
- local wound exploration under direct vision may determine lack of peritoneal penetration (not reliable in inexperienced hands) with the following exceptions:
  - thoracoabdominal region (may cause pneumothorax)
  - back or flanks (muscles too thick)

Management
- general: ABCs, fluid resuscitation, and stabilization
- gunshot wounds always require laparotomy

Genitourinary Tract Injuries
- see Urology, U34

Etiology
- blunt trauma: often associated with pelvic fractures
  - upper tract
    - renal
      - contusions (minor injury – parenchymal ecchymoses with intact renal capsule)
      - parenchymal tears/laceration: non-communicating (hematoma) vs. communicating (urine extravasation, hematuria)
    - ureter: rare, at uretero-pelvic junction
  - lower tract
    - bladder
      - extraperitoneal rupture of bladder from pelvic fracture fragments
      - intraperitoneal rupture of bladder from trauma and full bladder
    - urethra
      - posterior urethral injuries: MVCs, falls, pelvic fractures
      - anterior urethral injuries: blunt trauma to perineum, straddle injuries/direct strikes
  - external genitalia
    - penetrating trauma
      - damage to: kidney, bladder, ureter (rare), external genitalia
  - acceleration/deceleration injury
    - renal pedicle injury: high mortality rate (laceration and thrombosis of renal artery, renal vein, and their branches)
  - iatrogenic
    - ureter and urethra (from instrumentation)

History
- mechanism of injury
- hematuria (microscopic or gross), blood on underwear
- dysuria, urinary retention
- history of hypotension

Physical Exam
- abdominal pain, flank pain, CVA tenderness, upper quadrant mass, perineal lacerations
- DRE: sphincter tone, position of prostate, presence of blood
- scrotum: ecchymoses, lacerations, testicular disruption, hematomas
- bimanual exam, speculum exam
- extraperitoneal bladder rupture: pelvic instability, suprapubic tenderness from mass of urine or extravasated blood
- intraperitoneal bladder rupture: acute abdomen
- urethral injury: perineal ecchymosis, scrotal hematoma, blood at penile meatus, high riding prostate, pelvic fractures
Investigations
- urethra: retrograde urethrography
- bladder: U/A, CT scan, urethrogram ± retrograde cystoscopy ± cystogram (distended bladder + post-void)
- ureter: retrograde ureterogram
- renal: CT scan (best, if hemodynamically stable), intravenous pyelogram

Management
- urology consult
- renal
  - minor injuries: conservative management
    - bedrest, hydration, analgesia, antibiotics
  - major injuries: admit
    - conservative management with frequent reassessments, serial U/A ± re-imaging
    - surgical repair (exploration, nephrectomy): hemodynamically unstable or continuing to bleed
      >48 h, major urine extravasation, renal pedicle injury, all penetrating wounds and major
      lacerations, infections, renal artery thrombosis
- ureter
  - ureteroureterostomy
- bladder
  - extraperitoneal
    - minor rupture: Foley drainage x 10-14 d
  - major rupture: surgical repair
  - intraperitoneal
    - drain abdomen and surgical repair
- urethra
  - anterior: conservative, if cannot void, Foley or suprapubic cystostomy and antibiotics
  - posterior: suprapubic cystostomy (avoid catheterization) ± surgical repair

Orthopedic Injuries
- see Orthopedic Surgery (see Shoulder OR11, Knee OR32, Wrist OR21, Ankle OR38)

Goals of ED Treatment
- diagnose potentially life/limb threatening injuries
- reduce and immobilize fractures (cast/splint) as appropriate
- provide adequate pain relief
- arrange proper follow-up if necessary

History
- use SAMPLE, mechanism of injury may be very important

Physical Exam
- look (inspection): "SEADS" swelling, erythema, atrophy, deformity, and skin changes (e.g. bruises)
- feel (palpation): all joints/bones for local tenderness, swelling, warmth, crepitus, joint effusions, and
  subtle deformity
- move: joints affected plus those above and below injury – active ROM preferred to passive
- neurovascular status: distal to injury (before and after reduction)

LIFE- AND LIMB-THREATENING INJURIES

Table 10. Life- and Limb-Threatening Orthopedic Injuries

<table>
<thead>
<tr>
<th>Life-Threatening Injuries (usually blood loss)</th>
<th>Limb-Threatening Injuries (usually interruption of blood supply)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Major pelvic fractures</td>
<td>Fracture/dislocation of ankle (talar AVN)</td>
</tr>
<tr>
<td>Traumatic amputations</td>
<td>Crush injuries</td>
</tr>
<tr>
<td>Massive long bone injuries and associated fat emboli syndrome</td>
<td>Compartment syndrome</td>
</tr>
<tr>
<td>Vascular injury proximal to knee/elbow</td>
<td>Open fractures</td>
</tr>
</tbody>
</table>

Open Fractures
- communication between fracture site and external surface of skin – increased risk of osteomyelitis
- remove gross debris, irrigate, cover with sterile dressing – formal irrigation and debridement often done in the OR
- control bleeding with pressure (no clamping)
- splint
- antibiotics (1st generation cephalosporin and aminoglycoside) and tetanus prophylaxis
- standard of care is to secure definitive surgical management within 6 h, time to surgery may vary from case-to-case
**Vascular Injuries**
- realign limb/apply longitudinal traction and reassess pulses (e.g. Doppler probe)
- surgical consult
- direct pressure if external bleeding

**Compartment Syndrome**
- when the intracompartmental pressure within an anatomical area (e.g. forearm or lower leg) exceeds the capillary perfusion pressure, eventually leading to muscle/nerve necrosis
- clinical diagnosis: maintain a high index of suspicion
  - pain out of proportion to the injury
  - pain worse with passive stretch
  - tense compartment
  - look for "the 6 Ps" (note: radial pulse pressure is 120/80 mmHg while capillary perfusion pressure is 30 mmHg, seeing any of the 6Ps indicates advanced compartment syndrome, therefore do not wait for these signs to diagnose and treat)
- requires prompt decompression: remove constrictive casts, dressings; emergent fasciotomy may be needed

**UPPER EXTREMITY INJURIES**
- anterior shoulder dislocation
  - axillary nerve (lateral aspect of shoulder) and musculocutaneous nerve (extensor aspect of forearm) at risk
  - seen on lateral view: humeral head anterior to glenoid
  - reduce (traction, scapular manipulation), immobilize in internal rotation, repeat x-ray, out-patient follow-up with orthopedics
  - with forceful injury, look for fracture
- Colles’ fracture
  - distal radius fracture with dorsal displacement from "Fall on Outstretched Hand" (FOOSH)
  - AP film: shortening, radial deviation, radial displacement
  - lateral film: dorsal displacement, volar angulation
  - reduce, immobilize with splint, out-patient follow-up with orthopedics or immediate orthopedic referral if complicated fracture
  - if involvement of articular surface, emergent orthopedic referral
- scaphoid fracture
  - tenderness in anatomical snuff box, pain on scaphoid tubercle, pain on axial loading of thumb
  - negative x-ray: thumb spica splint, repeat x-ray in 1 wk ± CT scan/bone scan
  - positive x-ray: thumb spica splint x 6-8 wk, repeat x-ray in 2 wk
  - risk of AVN of scaphoid if not immobilized
  - outpatient orthopedics follow-up

**LOWER EXTREMITY INJURIES**
- ankle and foot fractures
  - see Ottawa Ankle and Foot Rules
- knee injuries
  - see Ottawa Knee Rules
  - avulsion of the base of 5th metatarsal
  - occurs with inversion injury
  - supportive tensor or below knee walking cast for 3 wk
- calcaneal fracture
  - associated with fall from height
  - associated with axial loading (other injuries may involve ankles, knees, hips, pelvis, lumbar spine)

**A Knee x-ray Examination is Required only for Acute Injury Patients with one or more of:**
- Age 55 yr or older
- Tenderness at head of fibula
- Isolated tenderness of patella
- Inability to flex to 90º
- Inability to bear weight both immediately and in the ED (four steps)

**Figure 8. Carpal bones**
© Elisheva Marcus

**Figure 9. Ottawa Knee Rules**
Wound Management

Goals of ED Treatment
- identify injuries and stop any active bleeding – direct pressure
- manage pain
- wound examination and exploration (history and physical)
- cleansing ± antibiotic and tetanus prophylaxis
- closure and dressing

Tetanus Prophylaxis
- both tetanus toxoid (Td) and immunoglobulin (TIG) are safe in pregnancy

Table 11. Guidelines for Tetanus Prophylaxis for Wounds

<table>
<thead>
<tr>
<th>Vaccination History</th>
<th>Clean, Minor Wounds</th>
<th>All Other Wounds*</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unknown or fewer than 3 doses</td>
<td>Tdap or Td(^1)</td>
<td>TIG</td>
</tr>
<tr>
<td>3 or more doses</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

*Such as, but not limited to, wounds contaminated with dirt, feces, soil, and saliva; puncture wounds; avulsions; and wounds resulting from missiles, crushing, burns, and frostbite

1Tdap is preferred to Td for adults who have never received Tdap. Single antigen tetanus toxoid (TT) is no longer available in the United States

9Yes, if more than ten years since the last tetanus toxoid-containing vaccine dose

Bruises
- non-palpable = ecchymosis
- palpable collection (not swelling) = hematoma following blunt trauma
- assess for coagulopathy (e.g. liver disease), anticoagulant use

Abrasions
- partial to full thickness break in skin
- management
  - clean thoroughly with brush to prevent foreign body impregnation ± local anesthetic antiseptic ointment (Polysporin* or Vaseline*) for 7 d for facial and complex abrasions tetanus prophylaxis

Lacerations
- see Plastic Surgery, PL23
- consider every structure deep to a laceration injured until proven otherwise
- in hand injury patients, include the following in history: handedness, occupation, mechanism of injury, previous history of injury

An ankle radiographic series is required only if there is any pain in malleolar zone and any of these findings:
1. Bony tenderness at A or
2. Bony tenderness at B or
3. Inability to bear weight both immediately and in ED

A radiographic series is required only if there is any pain in midfoot zone and any of these findings:
1. Bony tenderness at C or
2. Bony tenderness at D or
3. Inability to bear weight both immediately and in ED

</tr>
</tbody>
</table>

- differential can be focused anatomically by location of pain: RUQ, LUQ, RLQ, LLQ, epigastric, periumbilical, diffuse

History
- pain: OPQRST
- review symptoms from GU, gynecological, GI, respiratory, and CV systems
- abdominal trauma/surgeries, most recent colonoscopy

Physical Exam
- vitals, abdominal (including DRE, CVA tenderness), pelvic/genital, respiratory, and cardiac exams as indicated by history

Investigations
- ABCs, do not delay management and consultation if patient unstable
- labs: CBC, electrolytes, glucose, BUN/Cr, U/A ± liver enzymes, LFTs, lipase, β-hCG, ECG, troponins, ± VBG/lactate
- AXR: look for calcifications, free air, gas pattern, air fluid levels
- CXR upright: look for pneumoperitoneum (free air under diaphragm), lung disease
- U/S: biliary tract, ectopic pregnancy, AAA, free fluid
- CT: trauma, AAA, pancreatitis, nephro-/uro lithiasis, appendicitis, and diverticulitis

- Be vigilant: alcoholics, very young or elderly patients, and immunosuppressed patients often present atypically
- Old age, pregnancy (T3), and chronic corticosteroid use can blunt peritoneal findings, so have an increased level of suspicion for an intra-abdominal process in these individuals

- Unstable patients should not be sent for imaging

- Early wound irrigation and debridement are the most important factors in decreasing infection risk

- Alternatives to Sutures
- Tissue glue
- Steristrips®
- Staples

- If elevated AST and ALT Think hepatocellular injury
- AST > ALT alcohol-related
- ALT > AST viral, drug, toxin

- If elevated ALP and GGT Think biliary tree obstruction
Approach to Common ED Presentations

Management
• NPO, IV, NG tube, analgesics, consider antibiotics and anti-emetics
• growing evidence that small amounts of opioid analgesics improve diagnostic accuracy of physical exam of surgical abdomen
• consult as necessary: general surgery, vascular surgery, gynecology, etc.

Disposition
• admission: surgical abdomen, workup of significant abnormal findings, need for IV antibiotics or pain control
• discharge: patients with a negative lab and imaging workup who improve clinically during their stay; instruct the patient to return if severe pain, fever, or persistent vomiting develops

Acute Pelvic Pain

Etiology
• gynecological
  • ovaries: ruptured ovarian cysts (most common cause of pelvic pain), ovarian abscess, ovarian torsion (rare, 50% will have ovarian mass)
  • fallopian tubes: salpingitis, tubal abscess, hydrosalpinx
  • uterus: leiomyomas (uterine fibroids) – especially with torsion of a pedunculated fibroid or in a pregnant patient (degeneration), PID, endometriosis
  • other: ectopic pregnancy (ruptured/expanding/leaking), spontaneous abortion (threatened or incomplete), endometriosis and dysmenorrhea, sexual or physical abuse
• non-gynecological (see causes of lower abdominal pain above)

History and Physical Exam
• pain: OPQRST
• associated symptoms: vaginal bleeding, discharge, dyspareunia, bowel and/or bladder symptoms
• pregnancy and sexual history
• vitals
• gynecological exam: assess for cervical motion tenderness/“chandelier sign” (suggests PID)
• abdominal exam

Investigations
• β-hCG for all women of childbearing age
• CBC and differential, electrolytes, glucose, Cr, BUN, G&S, PTT/INR
• urinalysis to rule out urologic causes
• vaginal and cervical swabs for C&S during physical exam
• pelvic and abdominal U/S: evaluate adnexa, thickness of endometrium, pregnancy, free fluid or masses in the pelvis
• Doppler flow studies for ovarian torsion

Management
• general: analgesia, determine if admission and consults are needed
• specific:
  • ovarian cysts
    • unruptured or ruptured, and hemodynamically stable: analgesia and follow-up
    • ruptured with significant hemoperitoneum: may require surgery
  • ovarian torsion: surgical detorsion or removal of ovary
  • uncomplicated leiomyomas, endometriosis, and secondary dysmenorrhea can usually be treated on an outpatient basis, discharge with gynecology follow-up
  • PID: broad spectrum antibiotics

Disposition
• referral: gynecological or obstetrical causes requiring surgical intervention, requiring admission, or oncological in nature
• admission: patients requiring surgery, IV antibiotics/pain management
• discharge: negative workup and resolving symptoms; give clear instructions for appropriate follow-up

Altered Level of Consciousness

Definitions
• altered mental status: collective, non-specific term referring to change in cognitive function, behaviour, or attentiveness, including:
  • delirium (see Psychiatry, PS22)
  • dementia (see Psychiatry, PS23)
  • lethargy: state of decreased awareness and alertness (patient may appear wakeful)
  • stupor: unresponsiveness but rousable
  • coma: a sleep-like state, not rousable to consciousness
MANAGEMENT OF ALTERED LOC

History
- obtain collateral from family, friends, police, paramedics, old chart, MedicAlert® bracelet, etc.
- onset and progression
  - antecedent trauma, seizure activity, fever
  - abrupt onset suggests CNS hemorrhage/ischemia, cardiac cause, or poisoning
  - progression over hours to days suggests progressive CNS lesion or toxic/metabolic cause
- determine patient’s baseline LOC
- past medical history (e.g. similar episode(s), depression, overdose)

Physical Exam
- ABCs, vitals including temperature; cardiac, respiratory, abdominal exams
- complete neurological exam; in particular, examination of the eyes (“PEARL” pupils equal and reactive to light)
- use the GCS to evaluate LOC (see Patient Assessment/Management, ER4)

Investigations
- blood work
  - serum glucose level, electrolytes, Cr, BUN, LFTs, serum osmolality, CBC, VBG, PT/PTT/INR, troponins
  - serum acetaminophen, and salicylate levels
- imaging
  - CXR, CT head
- other tests
  - ECG, U/A, UTox

Diagnosis
- administer appropriate universal antidotes
  - thiamine 100 mg IV if history of EtOH or patient looks malnourished
  - 50 mL D50W if hypoglycemic on finger-prick
  - naloxone 0.4 mg, up to 10 mg IV if opiate overdose suspected
- distinguish between structural and toxic-metabolic coma
- structural coma
  - pupils, extraocular movements, and motor findings, if present, are usually asymmetric
  - look for focal or lateralizing abnormalities
- toxic-metabolic coma
  - dysfunction at lower levels of the brainstem (e.g. caloric unresponsiveness)
  - respiratory depression in association with an intact upper brainstem (e.g. equal and reactive pupils; see exceptions in Table 13)
  - extraocular movements and motor findings are symmetric or absent
- essential to re-examine frequently because status can change rapidly
- diagnosis may become apparent only with the passage of time
- delayed deficit after head trauma suggestive of epidural hematoma (characteristic “lucid interval”)

<td></td>
</tr>
</tbody>
</table>

**History and Physical Exam**
- OPQRST, previous episodes and change in pattern
- cardiac risk factors (HTN, DM, dyslipidemia, smoking, FHx)
- vitals, cardiac, respiratory, peripheral vascular, abdominal exams

**Investigations**
- CBC, electrolytes, Cr, BUN, glucose, PTT/INR, cardiac biomarkers (troponins, CK)
- ECG: always compare with previous; may be normal in up to 50% of PE and acute MI
- CXR: compare with previous
- CT: if indicated (e.g. aortic dissection, PE)

**Management and Disposition**
- ABCs, O2, cardiac monitors, IV access
- treat underlying cause and involve consultants as necessary
- consider further observation/monitoring if unclear diagnosis or risk of dysrhythmia
- discharge: patients with a low probability of life-threatening illness due to resolving symptoms and negative workup; arrange follow-up and instruct to return if SOB or increased chest pain develops

</tr>
<tr>
<td>Esophagitis or GERD</td>
<td>Frequent heartburn, acid reflux, dysphagia, relief with antacids</td>
<td>Oral thrush or ulcers (rare)</td>
<td>None acutely</td>
<td>ABCs, PPI, avoid EOH, tobacco, trigger foods</td>
</tr>
<tr>
<td>Herpes Zoster</td>
<td>Abnormal skin sensation – itching/burning/pain – preceding rash by 1-5 d</td>
<td>None if early; maculopapular rash developing into vesicles and pustules that crust</td>
<td>Clinical diagnosis; direct immunofluorescence assay</td>
<td>ABCs, anti-virals, antiseptics, dressing; o/o ocular involvement/refer if necessary</td>
</tr>
<tr>
<td>MSK</td>
<td>History of injury</td>
<td>Reproduction of symptoms with movement or palpation (not specific – present in 25% of MI)</td>
<td>MSK injury or fracture on X-rays</td>
<td>ABCs, NSAIDs, rest, orthopedics consultation for fractures</td>
</tr>
<tr>
<td>Anxiety</td>
<td>Symptoms of anxiety, depression, history of psychiatric disorder; may coexist with physical disease</td>
<td>Tachycardia, diaphoresis, tremor</td>
<td>Diagnosis of exclusion</td>
<td>ABCs, arrange social supports, rule out suicidality and consider psychiatry consult</td>
</tr>
</tbody>
</table>

**Table 15. Comparison of Chest Pain Diagnoses**

**Approach to Common ED Presentations**

**Investigations**
- ECG: ischemia (15-lead if hypotensive, AV node involvement or inferior MI), serial troponin I (sensitive 6-8 h after onset), CK-MB, CXR
- V/Q scan, leg Doppler, CXR, echocardiography
- CT angio; CXR - wide hyper-resonance; breath sounds, decreased/absent in extremities, ± chest tube
- Echocardiography
- Wells’ criteria: D-dimer, CT pulmonary angiogram, V/Q scan, leg Doppler
- Urgent consult

**Management and Disposition**
- ABCs, aspirin, anticoagulation, and emergent cardiology consult to consider percutaneous intervention or thrombolytic
- ABCs, rule out MI, high dose NSAIDs ± colchicine; consult if chronic/recurrent or non-viral cause (e.g. SLE, renal failure, requires surgery)
- ABCs, if unstable, needle to 2nd ICS at MCL; urgent surgical consult / thoracostomy 4th ICS and chest tube
- ABCs, reduce BP and HR; classify type A (ascending aorta, urgent surgery) vs. B (not ascending aorta, medical) on CT angiography and urgent consult
- ABCs, cardiac surgery or cardiology consult, pericardiocentesis if unstable, treat underlying cause
- ABCs, early antibiotics, resuscitation, thoracics consult, NPO, consider chest tube
- ABCs, PPI, avoid EOH, tobacco, trigger foods
- ABCs, anti-virals, antiseptics, dressing; o/o ocular involvement/refer if necessary
- ABCs, NSAIDs, rest, orthopedics consultation for fractures

**Conclusions**
- Among patients with suspected ACS presenting to emergency departments, the initial history, physical examination, and electrocardiogram alone did not confirm or exclude the diagnosis of ACS. Instead, the HEART or TIMI risk scores, which incorporate the first cardiac troponin, provided more diagnostic information.

Headache

- see Neurology, N44

Etiology

- common and less serious
  - common migraine (without aura)/classic migraine (with aura)
    - common: unilateral, throbbing, aggravated by activity, moderate/severe intensity, N/V, photo-/phonophobia
    - classic: fully reversible aura symptoms that precede headache, e.g. flashing lights, pins and needles (paresthesia), loss of vision, dysarthria
    - treatment: simple analgesics (NSAIDs, acetaminophen, aspirin), antiemetics, triptans
    - family doctor to consider prophylactic treatment
  - tension headache
    - bilateral, non-throbbing, not aggravated by routine physical activity, mild-moderate intensity.
    - can last between 30 min to 7 d
    - triggered with stress, sleep deprivation
    - treatment: modify stressor(s), simple analgesics (NSAIDs, acetaminophen, aspirin)

- less common but potentially fatal
  - subarachnoid hemorrhage (SAH) (see Neurosurgery, NS18)
    - sudden onset, “worst headache of life,” maximum intensity within minutes
    - increased pain with exertion, N/V, meningeal signs
    - diagnosis
      - new generation CT 100% sensitive within 6 h of onset (hyperattenuating signal around Circle of Willis)
      - LP if suspected SAH and normal CT after 6 h
    - management: urgent neurosurgery consult

- Migraine
  - see Neurology, N44

**Common Therapeutic Approach to Severe Migraine**

- 1 L bolus of NS
- prochlorperazine 10 mg IV
- diphenhydramine 25 mg IV
- ketorolac 30 mg IV
- dexamethasone 10 mg IV
- Other options include haloperidol, metoclopramide, arginine, sumatriptan, analgesics

**Ottawa SAH Rule**

- Use for alert patients older than 15 yr with new severe non-traumatic headache reaching maximum intensity within 1 h
- Not for patients with new neurologic deficits, previous aneurysms, SAH, brain tumours, or history of recurrent headaches (≥3 episodes over the course of ≥6 mo)
- Investigate if ≥1 high-risk variables present:
  - Age ≥40 yr
  - Neck pain or stiffness
  - Witnessed loss of consciousness
  - Onset during exertion
  - Thunderclap headache (instantly peaking pain)
  - Limited neck flexion on examination
- Subarachnoid hemorrhage can be predicted with 100% sensitivity using this rule.

**Immediate Treatment of Acute MI**

- BEMOAN
  - β-blocker
  - Enoxaparin
  - Morphine
  - Oxygen
  - ASA
  - Nitroglycerin

**Validation of the Ottawa Subarachnoid Hemorrhage Rule in Patients with Acute Headache**

- CMAJ 2017;189:E1379-E1385
- Objectives: Validate the Ottawa SAH Rule in emergency department patients. Methods: Prospective cohort study at 6 university-affiliated tertiary-care hospital emergency departments in Canada from 2010-2014. Included alert, neurologically intact adult patients with headache peaking within 1 hour of onset. The rule was scored before investigations.
- Results: 1153/1743 potentially eligible patients were enrolled, 67 had subarachnoid hemorrhage. Ottawa SAH rule had 100% sensitivity and 13.6% specificity with similar neuroimaging rates (87%).
- Conclusions: The Ottawa SAH Rule was sensitive for identifying subarachnoid hemorrhage in otherwise alert and neurologically intact patients.

**Meningitis**

- Do not delay IV antibiotics for LP
- Deliver first dose of dexamethasone with or before first dose of antibiotic therapy
Approach to Common ED Presentations

- increased ICP
  - worse in morning, when supine or bending down, with cough or Valsalva
  - physical exam: neurological deficits, cranial nerve palsies, papilledema
  - diagnosis: CT head
  - management: consult neurosurgery
- meningitis (see Infectious Diseases, ID15)
  - flu-like symptoms (fever, N/V, malaise), meningeal signs, petechial rash
  - altered LOC and confusion
  - rule out increased ICP; if CT head and mental status normal, if no neurological signs and no papilledema, then do LP for diagnosis
  - treatment: early empiric antibiotics ± acyclovir, steroid therapy
- temporal arteritis (causes significant morbidity, blindness) (see Ophthalmology, OP35)
  - vasculitis of large and mid-sized arteries, gender 3:1 F:M, most commonly age >70 yr
  - headache, scalp tenderness, jaw claudication, arthralgia, myalgia, fever, malaise or weight loss
  - temporal artery tender on palpation, relative afferent pupillary defect (RAPD), optic disc edema on fundoscopy
  - labs: elevated ESR, CRP
  - temporal artery biopsy is gold standard for diagnosis
  - associated with polymyalgia rheumatica
  - treatment: high-dose steroids immediately if suspected, no need to hold treatment until pathology results

Disposition
- admission: if underlying diagnosis is critical or emergent, if there are abnormal neurological findings, if patient is elderly or immunocompromised (atypical presentation), or if pain is refractory to oral medications
- discharge: assess for risk of narcotic misuse; most patients can be discharged with appropriate analgesia and follow-up with their family physician; instruct patients to return for fever, vomiting, neurologic changes, or increasing pain

Joint and Back Pain

JOINT PAIN (see Rheumatology, RH3)
- rule out life threatening causes e.g. septic joint (see Orthopedic Surgery, OR11)

History and Physical Exam
- history: recent trauma, drug use (anticoagulants, glucocorticoids)
- associated symptoms: fever, constitutional symptoms, skin lesions, conjunctivitis, urethritis
- patterns of joint involvement: polyarticular vs. monoarticular, symmetric vs. asymmetric
- inflammatory symptoms: morning stiffness ≥30 min, pain/stiffness that ease with activity, mid-day fatigue, soft tissue swelling
- non-inflammatory symptoms: morning stiffness <30 min, stiffness short-lived after inactivity, increasing pain with activity
- assess for pain with ROM, localized joint pain, effusion, erythema, warmth, swelling, inability to bear weight, fever; may indicate presence of septic joint

Investigations
- blood work: CBC, ESR, CRP, WBC, INR/PTT, blood cultures, urate
- joint x-ray ± contralateral joint for comparison
- bedside U/S to identify effusion
- test joint aspirate for: culture, WBC, polymuclear cells, glucose, Gram stain, crystals

Management
- septic joint: empiric IV antibiotics ± joint décompression and drainage
- crystalline synovitis: NSAIDs at high dose, colchicine within first 24 h, corticosteroids
  - do not use allopurinol, as it may worsen acute attack
- acute polyarthritis: NSAIDs, analgesics (acetaminophen ± opioids), local or systemic corticosteroids
- osteoarthritis: NSAIDs, acetaminophen
- soft tissue pain: allow healing with enforced rest ± immobilization
  - non-pharmacologic treatment: local heat or cold, electrical stimulation, massage
  - pharmacologic: oral analgesics, NSAIDs, muscle relaxants, corticosteroid injections, topical agents

BACK PAIN (see Family Medicine, FM37)
- rule out extraspinal emergencies: aortic dissection, AAA, PE, MI, retroperitoneal bleed, pancreatitis
- rule out spinal emergencies: osteomyelitis, cauda equina, epidural abscess or hematoma, spinal fracture

History and Physical Exam
- evaluate risk for fracture (osteoporosis, age), infection (IV drug user, recent spinal intervention, immnosuppression), cancer, vascular causes (cardiac risk factors)
- typical musculoskeletal back pain is moderate, worse with movement or cough with no visceral symptoms
- assess vital signs, perform precordial, abdominal, and neurologic examination of lower extremities
Investigations
- reserve imaging for suspicion of emergencies, metastases, and patients at high risk of fracture, infection, cancer, or vascular causes
- WBC, ESR, CRP, UA

Management
- treat underlying cause
- lumbosacral strain and disc herniation: analgesia and continue daily activities as much as tolerated; discuss red flags and organize follow-up
- spinal infection: early IV antibiotics and ID consultation
- cauda equina: dexamethasone, early neurosurgical consultation

Seizures
- see Neurology, N18

Definition
- paroxysmal alteration of behaviour and/or EEG changes resulting from abnormal, excessive activity of neurons
- status epilepticus: continuous or intermittent seizure activity for greater than 5 min without regaining consciousness (life threatening)

Categories
- generalized seizure (consciousness always lost): tonic/clonic, absence, myoclonic, atonic
- partial seizure (focal): simple partial, complex partial
- causes: primary seizure disorder, structural (trauma, intracranial hemorrhage, infection, increased ICP), metabolic disturbance (hypo-/hyperglycemia, hypo-/hypernatremia, hypocalcemia, hypomagnesemia, toxins/drugs)
- differential diagnosis: syncope, stroke/TIA, pseudoseizures, migraines, movement disorders, narcolepsy/cataplexy

History and Physical Exam
- history of seizures, identify potential precipitants (illness, alcohol use, sleep deprivation)
- preceding aura, rapid onset, brief duration, alterations in consciousness, tonic-clonic movements, and post-ictal symptoms would suggest a seizure
- common signs include loss of bladder/bowel control, tongue biting, emesis and aspiration
- perform vitals, complete neurologic examination and look for injuries to head, spine, and shoulder (dislocations)

History and Physical Exam

- acute SOB is often due to a relatively limited number of conditions; associated symptoms and signs are key to the appropriate diagnosis
  - substernal chest pain with cardiac ischemia
  - fever, cough, and sputum with respiratory infections
  - urticaria with anaphylaxis
  - wheezing with acute bronchospasm
  - environmental or occupational exposures
- dyspnea may be the sole complaint and the physical exam may reveal few abnormalities (e.g. PE, pneumothorax)
- vitals including pulse oximetry
  - wheeze and stridor (airway) vs. crackles (parenchymal), JVP, and murmurs

Investigations

- blood work
  - CBC and differential (hematocrit to exclude anemia), electrolytes, consider ABG/VBG
  - serial cardiac enzymes and ECG if considering cardiac source
  - Wells scores to consider appropriateness of D-dimer
- imaging
  - CXR (hyperinflation and bullous disease suggestive of obstructive lung disease, or changes in interstitial markings consistent with inflammation, infection, or interstitial fluid)
  - CT chest usually is not indicated in the initial evaluation of patients with dyspnea, but can be valuable in patients with interstitial lung disease, occult emphysema, or chronic thromboembolic disease (i.e. PE)

Management of Life-Threatening Dyspnea NYD

- see Primary and Secondary Surveys, ER2
- treat underlying cause

Disposition

- the history and physical exam lead to accurate diagnoses in patients with dyspnea in approximately two-thirds of cases; the decision to admit or discharge should be based on the underlying disease process identified
  - consider intubation in CO2 retainer (e.g. COPD)
  - if discharging, organize follow-up and educate regarding signs to return to hospital

Syncope

Definition

- sudden, transient loss of consciousness and postural tone with spontaneous recovery
- usually caused by generalized cerebral or reticular activating system (brainstem) hypoperfusion

Etiology

- cardiogenic: dysrhythmia, outflow obstruction (e.g. PE, pulmonary HTN), MI, valvular disease
- non-cardiogenic: peripheral vascular (hypovolemia), vasovagal, cerebrovascular disorders, CNS, metabolic disturbances (e.g. EtOH intoxication)

History

- gather details from witnesses, and clarify patient's experience (e.g. dizziness, ataxia, or true syncope)
  - two key historical features: prodrome and situation (setting, patient posture)
  - distinguish between syncope and seizure (see Neurology, N19)
Approach to Common ED Presentations

- some patients may have myoclonic jerks with syncope – NOT a seizure
  - signs and symptoms during presyncope, syncope, and postsyncope
  - past medical history, drugs
  - think anatomically in differential: pump (heart), blood, vessels, brain
- syncope is cardiogenic until proven otherwise if
  - there is sudden loss of consciousness with no warning or prodrome
  - syncope is accompanied by chest pain

Physical Exam
- postural BP and HR
- cardiac, respiratory, and neurological exams
- examine for signs of secondary injury caused by syncopal episode (e.g. head injury)

Investigations
- ECG (tachycardia, bradycardia, blocks, Wolff-Parkinson White, long QT interval, Brugada Syndrome, RV strain), bedside glucose
- consider blood work: CBC, electrolytes, BUN/Cr, troponin, Ca^{2+}, Mg^{2+}, β-hCG, D-dimer
- consider toxicology screen

Management
- ABCs, IV, O2, monitor
- cardiogenic syncope: admit to medicine/cardiology
- low risk syncope: discharge with follow-up as indicated by cause (non-cardiogenic syncope may still be admitted)

Disposition
- decision to admit is based on etiology
- most patients will be discharged
- on discharge, instruct patient to follow-up with family physician
  - educate about avoiding orthostatic or situational syncope
  - evaluate the patient for fitness to drive or work
  - patients with recurrent syncope should avoid high-risk activities (e.g. driving)

Epidemiology
- 1 in 5 women and 1 in 71 men will be sexually assaulted in their lifetime; only 7% are reported

General Approach
- ABCs, treat acute, serious injuries; physician priority is to treat medical issues and provide clearance
- ensure patient is not left alone and provide ongoing emotional support
- obtain consent for medical exam and treatment, collection of evidence, disclosure to police (notify police as soon as consent obtained)
- Sexual Assault Kit (document injuries, collect evidence) if <72 h since assault
- label samples immediately and pass directly to police
- offer community crisis resources (e.g. shelter, hotline)
- do not report unless victim requests or if <16 yr old (legally required)

History
- ensure privacy for the patient – others should be asked to leave
- questions to ask: who, when, where did penetration occur, what happened, any weapons, or physical assault?
- post-assault activities (urination, defecation, change of clothes, shower, douche, etc.)
- gynecologic history
  - gravidity, parity, last menstrual period
  - contraception use
  - last voluntary intercourse (sperm motile 6-12 h in vagina, 5 d in cervix)
- medical history: acute injury/illness, chronic diseases, psychiatric history, medications, allergies, etc.

Physical Exam
- never re-traumatize a patient with the examination
- general examination
  - mental status
  - sexual maturity
  - patient should remove clothes and place in paper bag
  - document abrasions, bruises, lacerations, torn frenulum/broken teeth (indicates oral penetration)
Approach to Common ED Presentations

**Investigations**
- Pelvic exam and specimen collection
  - Ideally before urination or defecation
  - Examine for seminal stains, hymen, signs of trauma
  - Collect moistened swabs of dried seminal stains
  - Pubic hair combings and cuttings
  - Speculum exam
    - Lubricate with water only
    - Vaginal lacerations, foreign bodies
    - Pap smear, oral/cervical/rectal culture for gonorrhea and chlamydia
    - Posterior fornix secretions if present or aspiration of saline irrigation
    - Immediate wet smear for motile sperm
    - Air-dried slides for immotile sperm, acid phosphatase, ABO group
  - Finger-nail scrapings and saliva sample from victim

- Investigations
  - Venereal Disease Research Lab (VDRL): repeat in 3 mo if negative
  - Serum β-hCG
  - Blood for ABO group, Rh type, baseline serology (e.g. hepatitis, HIV)

**Management**
- Involve local/regional sexual assault team (sexual assault forensic examiner or sexual assault nurse examiner)
- Medical
  - Suture lacerations, tetanus prophylaxis
  - Gynecology consult for foreign body, complex lacerations
  - Assume positive for gonorrhea and chlamydia
    - Management: azithromycin 1 g PO x 1 dose (alt: doxycycline 100 mg PO bid x 10 d) and ceftriaxone 250 mg IM x 1 dose
  - May start prophylaxis for hepatitis B and HIV
  - Pre and post counselling for HIV testing
  - Pregnancy prophylaxis offered
    - Levonorgestrel 1.5 g PO STAT (Plan B®)
- Psychological
  - High incidence of psychological sequelae
  - Have victim change and shower after exam completed

**Disposition**
- Discharge if injuries/social situation permit
- Follow-up with physician in rape crisis centre within 24 h for repeat pregnancy and STI testing.
- Best if patient does not leave ED alone

**DOMESTIC VIOLENCE**
- Women are usually the victims, but male victimization also occurs
- Identify the problem (need high index of suspicion)
  - Suggestive injuries (bruises, sprains, abrasions, occasionally fractures, burns, or other injuries; often inconsistent with history provided)
  - Somatic symptoms (chronic and vague complaints)
  - Psychosocial symptoms
  - Clinician impression (your ‘gut feeling’, e.g. overbearing partner that won’t leave patient’s side)
- If disclosed, be supportive and assess danger
- Patient must consent to follow-up investigation/reporting (unless for children)

**Management**
- Treat injuries and document findings
- Ask about sexual assault and children at home (encourage notification of police)
- Safety plan with good follow-up with family physician/social worker
Medical Emergencies

Anaphylaxis and Allergic Reactions

Etiology
- anaphylaxis is an exaggerated immune mediated hypersensitivity reaction that leads to systemic histamine release, increased vascular permeability, and vasodilation; regardless of the etiology, the presentation and management of anaphylactic reactions are the same
- allergic (re-exposure to allergen)
- non-allergic (e.g. exercise induced)

Diagnostic Criteria
- anaphylaxis is highly likely with any of:
  1. acute onset of an illness (min to hrs) with involvement of the skin, mucosal tissue and at least one of
     - respiratory compromise (e.g. dyspnea, wheeze, stridor, hypoxemia)
     - hypotension/end-organ dysfunction (e.g. hypotonia, collapse, syncope, incontinence)
  2. two or more of the following after exposure to a LIKELY allergen for that patient (min to hrs)
     - involvement of the skin-mucosal tissue
     - respiratory compromise
     - hypotension or associated symptoms
     - persistent gastrointestinal symptoms (e.g. crampy abdominal pain, vomiting)
  3. hypotension after exposure to a KNOWN allergen for that patient (min to h)
     - management is also appropriate in cases which do not fulfill criteria, but who have had previous episodes of anaphylaxis
     - life-threatening differentials for anaphylaxis include asthma and septic shock
     - angioedema may mimic anaphylaxis but tends not to improve with standard anaphylaxis treatment

Management
- moderate reaction: generalized urticaria, angioedema, wheezing, tachycardia
  - epinephrine (1:1000) 0.3-0.5 mg (IM in anterolateral thigh)
  - antihistamines: diphenhydramine (Benadryl®) 25-50 mg PO/IV
  - salbutamol (Ventolin®) 1 cc via MDI
- severe reaction/evolution: severe wheezing, laryngeal/pulmonary edema, shock
  - ABCs, may need definitive airway (e.g. ETT) due to airway edema
  - epinephrine (1:1000) 1-10 µg/min IV (or via ETT if no IV access) titrated to desired effect
  - antihistamines: diphenhydramine (Benadryl®) 50 mg IV (~1 mg/kg)
  - glucocorticoids: methylprednisolone 125-250 mg IV or prednisone/prednisolone 40-60 mg PO
  - large volumes of crystalloid may be required

Disposition
- monitor for 4-8 h in ED (minimum) and arrange follow-up with family physician in 24-48 h
- can have second phase (biphasic) reaction up to 72 h later, patient may need to be supervised
- educate patient on avoidance of allergens
  - medications
    - H1 antagonist (cetirizine 10 mg PO OD or Benadryl® 50 mg PO q4-6h x3d)
    - H2 antagonist (ranitidine 150 mg PO OD x3d)
    - corticosteroid (prednisone 50 mg PO OD x5d) to prevent secondary reaction

Asthma
- see Respiriology, R7
- chronic inflammatory airway disease with episodes of bronchospasm and inflammation resulting in reversible airflow obstruction

History and Physical
- find cause(s) of asthma exacerbation (viral, environmental, etc.)
- history of asthma control; severity of exacerbations (ICU, intubation history)
- signs of respiratory distress
- vitals, specifically O2

Investigations
- peak flow metre
- ± ABG if in severe respiratory distress
- CXR if diagnosis in doubt to rule out pneumonia, pneumothorax, etc.

</tbody>
</table>

### Disposition
- discharge safe in patients with FEV₁ or PEF >60% predicted, and may be safe if FEV₁ or PEF 40-60% predicted based on patient’s risk factors for recurrence of severe attack
- risk factors for recurrence: frequent ED visits, frequent hospitalizations, recent steroid use, recent exacerbation, poor medication compliance, prolonged use of high dose β-agonists
- β-agonist MDI with aerosol chamber 2-4 puffs q2-4h until symptoms controlled, then prn as needed
- initiate inhaled corticosteroids with aerochamber if not already prescribed
- if moderate to severe attack, administer prednisone 30-60 mg/d for 5-10 d with no taper
- counsel on medication adherence and educate on use of aerosolizer
- follow-up with primary care physician or asthma specialist

### Cardiac Dysrhythmias

- see Cardiology and Cardiac Surgery. C18

### Bradydysrhythmias and AV Conduction Blocks
- AV conduction blocks
  - 1st degree: prolonged PR interval (>200 msec), no treatment required
  - 2nd degree
    - Mobitz I: gradual prolongation of PR interval then dropped QRS complex, usually benign
    - Mobitz II: PR interval constant with dropped QRS complex, can progress to 3rd degree AV block
  - 3rd degree: P wave unrelated to QRS complex, PP and RR intervals constant
    - atropine and transcutaneous pacing (atropine with caution)
    - if transcutaneous pacing fails consider IV dopamine, epinephrine
  - long-term treatment for Mobitz II and 3rd degree block – internal pacemaker

- sinus bradycardia (rate <60 bpm)
  - can be normal (especially in athletes)
  - causes: vagal stimulation, vomiting, myocardial infarction/ischemia, increased ICP, sick sinus node, hypothyroidism, drugs (e.g. β-blockers, calcium channel blockers)
  - treat if symptomatic (hypotension, chest pain)
    - acute: atropine 2-3 transcutaneous pacing
    - sick sinus: transcutaneous pacing
    - drug induced: discontinue/reduce offending drug, consider antihypertensives

### Supraventricular Tachydysrhythmias (narrow QRS)
- sinus tachycardia (rate >100 bpm)
  - causes: increased sympathetic tone, drugs, fever, hypotension, anemia, thyrotoxicosis, MI, PE, emotional, pain, etc.
  - search for and treat underlying cause, consider β-blocker if symptomatic
- regular rhythm (i.e. not sinus tachycardia)
  - vagal maneuvers (carotid massage, Valsalva), adenosine 6 mg IV push, if no conversion give 12 mg, can repeat 12 mg dose once
  - rhythm converts: probable re-entry tachycardia (AVNRT more common than AVRT)
    - monitor for recurrence
    - treat recurrence with adenosine or other acting medications
- rhythm does not convert: atrial flutter, ectopic atrial tachycardia, junctional tachycardia
  - rate control (diltiazem, β-blockers) and consult cardiology
- irregular rhythm
  - probable AFib, atrial flutter, or multifocal atrial tachycardia
  - rate control (diltiazem, β-blockers)
Atrial Fibrillation
- most common sustained dysrhythmia; no organized P waves (atrial rate >300/min), irregularly irregular heart rate, narrow QRS (typically)
- etiology: HTN, CAD, thyrotoxicosis, EtOH (holiday heart), valvular disease, pericarditis, cardiomyopathy, sick sinus syndrome
- treatment principles: stroke prevention, treat symptoms, identify/treat underlying cause
- decreases cardiac output by 20-30% (due to loss of organized atrial contractions)
- acute management
  - if unstable: immediate synchronized cardioversion
  - if onset of AFib is >48 h: rate control, anticoagulate 3 wk prior to and 4 wk after cardioversion, or do transesophageal echocardiogram to rule out clot
  - if onset <48 h or already anticoagulated: may cardiovert
- electrical cardioversion: synchronized direct current (DC) cardioversion
- chemical cardioversion: procainamide, flecainide, propafenone
- long-term management: rate or rhythm control, consider anticoagulation (see Cardiology and Cardiac Surgery, CHADS2 score C20)

Ventricular Tachydysrhythmias (wide QRS)
- VTach (rate usually 140-200 bpm)
  - definition: 3 or more consecutive ventricular beats at >100 bpm
  - etiology: CAD with MI is most common cause
  - treatment: sustained VTach (>30 s) is an emergency
    - hemodynamic compromise: synchronized DC cardioversion
    - no hemodynamic compromise: synchronized DC cardioversion, amiodarone, procainamide
- VFib: call a code blue, follow ACLS for pulseless arrest
- Torsades de pointes
  - looks like VTach but QRS ‘rotates around baseline’ with changing axis and amplitude (twisted ribbon)
  - etiology: prolonged QT due to drugs (e.g. quinidine, TCAs, erythromycin, quinolones), electrolyte imbalance (hypokalemia, hypomagnesemia), congenital
  - treatment
    - IV Mg²⁺, temporary overdrive pacing, isoproterenol
    - correct cause of prolonged QT

Acute Exacerbation of COPD (AECOPD)
- see Respirology, Chronic Management of COPD R9
- progressive development of irreversible airway obstruction, typically caused by smoking

History and Physical Exam
- cardinal symptoms of AECOPD: increased dyspnea, increased coughing frequency or severity, increased sputum volume or purulence
- triggers: virus, pneumonia, urinary tract infection, PE, CHF, MI, drugs
- characterize previous episodes and hospitalizations, smoking history
- vital signs, LOC, signs of respiratory distress, respiratory exam

Investigations
- CBC, electrolytes, CXR, ECG, consider ABG
- PFTs are NOT useful in managing acute exacerbations

Management
- oxygen: keep O₂ sat 88-92% (be aware when giving O₂ to chronic hypercapnic/CO₂ retainers but do not withhold O₂ if hypoxic)
- bronchodilators: short-acting β-agonist (salbutamol 4-8 puffs via MDI with spacer q15min x3 prn) ± short-acting anticholinergic (ipratropium 0.5 mg via MDI q30min x3 prn)
- steroids: prednisone 40-60 mg PO for 7-14 d, or methylprednisolone 1-2 mg/kg IV if severe exacerbation, or unable to take PO
- antibiotics: TMP-SMX, cephalosporins, respiratory quinolones (given if all 3 cardinal symptoms present or 2 cardinal symptoms with increased sputum purulence or mechanical ventilation)
- ventilation: apply noninvasive positive-pressure ventilation (CPAP or BiPAP) if severe distress or signs of fatigue, arterial pH <7.35, or hypercapnic
- if life-threatening, ICU admission for intubation and ventilation (chance of ventilation dependency)

Disposition
- no guidelines for admission - based on clinical judgement and comorbidities
- lower threshold to admit if comorbid illness (diabetes, CHF, CAD, alcohol abuse)
- if discharging, use antibiotics, taper steroids, up to 4-6 puffs qid of ipratropium and salbutamol and organize follow-up
Acute Decompensated Heart Failure (ADHF)

- see Cardiology and Cardiac Surgery, C34

**Etiology**
- causes of CHF: decreased myocardial contractility (ischemia, infarction, cardiomyopathy, myocarditis), pressure overload states (HTN, valve abnormalities, congenital heart disease), restricted cardiac output (myocardial infiltrative disease, cardiac tamponade)
- precipitants of acute decompensation of CHF
  - cardiac (ischemia, infarction, arrhythmia - Afib)
  - medications (β-blockers, CCBs, NSAIDs, steroids, non-compliance)
  - dietary (increased sodium and/or water intake)
  - high output (anemia, infection, pregnancy, hyperthyroid)
  - other (renal failure, hypertensive crisis, iatrogenic fluid overload - blood transfusions or IV fluids)

**Presentation**
- left-sided heart failure
  - dyspnea, SOB, orthopnea, PND, nocturia, fatigue, altered mental status, presyncope/syncope, angina, systemic hypotension
  - hypoxia, decreased air entry to lungs, crackles, S3 or S4, pulmonary edema (on CXR), pleural effusion (usually right-sided)
- right-sided heart failure
  - dependent bilateral pitting edema, JVP elevation and positive AJR, ascites, hepatomegaly
  - patients often present with a combination of right-sided and left-sided symptoms

**Investigations**
- blood work: CBC, electrolytes, AST, ALT, bilirubin, Cr, BUN, cardiac enzymes, brain natriuretic peptide
- CXR: most useful test (see sidebar)
- ECG: look for MI, ischemia (ST elevation/depression, T-wave inversion), LVH, atrial enlargement, conduction abnormalities
- bedside ultrasound: wall motion abnormalities, ejection fraction, rule out cardiac tamponade
- echocardiogram: LV function, structural heart disease
- rule out other serious diagnoses: PE, pneumothorax, pneumonia/empyema, acute exacerbations COPD

**Management**
- ABCs, may require intubation if severe hypoxia
- sit upright, cardiac monitoring, and continuous pulse oximetry
- saline lock IV, Foley catheter due to diuretic therapy
- 100% O2 by mask
- if poor response, may require BiPAP or intubation
- medical
  - diuretic (if volume overloaded): furosemide 0.5-1 mg/kg IV
  - vasodilators (if sBP >100): nitroglycerin 0.4 mg SL q5min prn ± topical Nitrodur® patch (0.4-0.8 mg/h)
  - if patient not responding to treatment or showing signs of ischemia (angina): nitroglycerine 5-10 µg/min IV, titrate to response
  - inotropes/vasopressors (if sBP <90)
    - without signs of shock: dobutamine 2.5 µg/kg/min IV, titrate up to sBP >90 mmHg
    - with signs of shock: norepinephrine 8-12 µg/min, titrate up to sBP >90 mmHg
- treat precipitating factor - e.g. rate control (β-blocker, calcium channel blockers) or rhythm-control (electrical or chemical cardioversion) if new Afib
- cardiology or medicine consult

**Precipitants of CHF Exacerbation**

**CHF on CXR**
- Pulmonary vascular redistribution
- Perihilar infiltrates
- Kerley B lines
- Alveolar edema, bilateral infiltrates
- May see cardiomegaly, pleural effusions
- Peribronchial cuffing
- Fissural thickening (fluid in fissure)

**Acute Treatment of CHF**
- LMNOP
  - Lasix® (furosemide)
  - Morphine
  - Nitroglycerin
  - Oxygen
  - Position (sit upright), Pressure (BiPAP)

**Hospital Management Required if**
- Acute MI
- Pulmonary edema or severe respiratory distress
- Severe complicating medical illness (e.g. pneumonia)
- Anasarca
- Symptomatic hypotension or syncope
- Refractory to outpatient therapy
- Thromboembolic complications requiring interventions
- Clinically significant dysrhythmias
- Inadequate social support for safe outpatient management
- Persistent hypoxia requiring supplemental oxygen
Venous Thromboembolism (VTE)

- see Respirology, R19

**Risk Factors**
- Virchow's triad: alterations in blood flow (venous stasis), injury to endothelium (smoking, HTN, surgery, catheter, trauma), hypercoagulable state (including pregnancy, use of OCP, malignancy)
- clinical risk factors (see sidebar)

**DEEP VEIN THROMBOSIS (DVT)**

**Presentation**
- calf pain, unilateral leg swelling/erythema/edema, palpable cord along the deep venous system on exam; can be asymptomatic
- clinical signs/symptoms are unreliable for diagnosis and exclusion of DVT; investigation often needed

**Investigations**
- use Wells' criteria for DVT to guide investigations (see Figure 12)
- D-dimer is only useful for ruling out DVT, and a D-dimer test result should only be considered in cases where a low-moderate risk patient has a negative test (high sensitivity)
- high risk of false positives: in elderly, infection, recent surgery, trauma, hemorrhage, late in pregnancy, liver disease, cancer
- U/S has high sensitivity & specificity for proximal clot but only 73% sensitivity for calf DVT (may need to repeat in 1 wk)
- if positive – treat for DVT regardless of risk
- if negative and low risk – rule out DVT
- if negative and moderate to high risk – repeat U/S in 5-7 d to rule out DVT

**Management**
- DOAC can be used in acute management of symptomatic DVT
  - rivaroxaban: 15 mg PO bid for first 21 d; 20 mg PO daily for remaining treatment (taken with food at the same time each day)
  - apixaban: 10 mg PO bid for first 7 d; 5 mg PO bid for remaining treatment
  - LMWH unless patient also has renal failure
  - dalteparin 200 IU/kg SC q24h or enoxaparin 1 mg/kg SC q24h
  - warfarin started at same time as LMWH (5 mg PO OD initially followed by dosing based on INR)
  - LMWH discontinued when INR has been therapeutic (2-3) for 2 consecutive days
  - consider thrombolyisis if extensive DVT threatening limb compromise
  - IVC filter or surgical thrombectomy considered if anticoagulation is contraindicated
  - duration of anticoagulation: 3 mo if transient coagulopathy; 6 mo if unprovoked DVT; life-long if ongoing coagulopathy

**PULMONARY EMBOLISM (PE)**

**Presentation**
- dyspnea, pleuritic chest pain, hemoptysis, tachypnea, cyanosis, hypoxia, fever
- clinical signs/symptoms are unreliable for diagnosis and exclusion of DVT; investigation often needed

**Investigations**
- use Wells' criteria for PE to guide investigations (see Figure 13)
- Wells' score alone can rule out PE in low risk patients (as determined by Wells’ criteria) unless patient is pregnant
- ECG and CXR are useful to rule out other causes (e.g. ACS, pneumonia, pericarditis) or to support diagnosis of PE
  - ECG changes in PE: sinus tachycardia, right ventricular strain (SIQ3T3), T wave inversions in anterior and inferior leads
  - CXR findings in PE: Hampton's hump (triangular density extending from pleura) or Westermark's sign (dilatation of vessels proximal to an obstruction, with collapse of vessels distal to obstruction, often with a sharp cutoff)
- D-dimer is only useful at ruling out a PE if it is negative in low-moderate risk patients (highly sensitive)
  - if positive D-dimer or high-probability patient, then pursue CT angiography or V/Q scan
- CT angiography has high sensitivity and specificity for PE, may also indicate an alternative diagnosis
  - V/Q scan useful in pulmonary, when CT angiography not available, or IV contrast contraindicated
- treatment of PE with anticoagulation and duration of treatment is the same as for DVT (see above)
- consider thrombolysis if extensive PE causing hemodynamic compromise or cardiogenic shock
- catheter-directed thrombolysis or surgical thrombectomy may be considered in massive PE or if anticoagulation is contraindicated
- often can be treated as outpatient, may require analgesia for chest pain (narcotic or NSAID)
- admit if hemodynamically unstable, require supplemental O₂, major comorbidities, lack of sufficient social supports, unable to ambulate, need invasive therapy
  - referral to medicine for coagulopathy and malignancy workup

**Figure 12. Approach to suspected DVT**

- Suspected (symptomatic) acute DVT
  - Compression U/S
    - Normal
      - Repeat U/S in 5 days
    - Inconclusive or inadequate study
      - DVT present
        - Venography or MRI
        - Treatment
    - DVT present
      - Treatment
    - DVT absent
      - No treatment

**Figure 13. Approach to suspected PE**

- Determine need to investigate via PERC score
  - Low D-dimer assay
    - <500 ng/mL
      - PE excluded
      - Negative
        - No treatment
    - >500 ng/mL
      - CT pulmonary angiogram (CT-PA)
      - Positive
        - PE confirmed
      - Negative
        - PE excluded
  - Moderate/High Wells’ Criteria
    - Positive ≥1/8
      - PE confirmed
    - Negative 0/8
      - PE excluded

---

**Diabetic Emergencies**

- see Endocrinology, E12

**Diabetic Ketoacidosis**

- triad of hyperglycemia, ketosis, and acidosis due to severe insulin deficiency and counter-regulatory hormone excess
- clinical feature
  - often young, Type 1 DM patients (may rarely be first presentation of undiagnosed Type 2 DM), with symptoms evolving within a day
  - early signs and symptoms: polyuria, polydipsia, malaise, nocturia, weight loss
  - late signs and symptoms
    - GI: anorexia, nausea, vomiting, abdominal pain
    - neurological: fatigue, drowsiness, stupor, coma
    - respiratory: Kussmaul's respiration, dyspnea (often due to acidosis), fruity ketotic breath
- investigations
  - blood work: CBC, electrolytes, Ca²⁺, Mg²⁺, PO₄³⁻, Cr, BUN, glucose, ketones, osmolality, AST/ALT/ALP, amylase, troponin
  - urine: glucose and ketones
  - ABG or VBG
  - ECG (MI is possible precipitant; electrolyte disturbances may predispose to dysrhythmia)
- management
  - rehydration
    - bolus of NS, then high rate NS infusion (be aware of overhydration and cerebral edema, especially in pediatric patients)
    - beware of a pseudohyponatremia due to hyperglycemia (add 3 Na⁺ per 10 glucose over 5.5 mmol/L)
Medical Emergencies

**Potassium**
- Essential to avoid hypokalemia: replace KCl (20 mEq/L if adequate renal function and initial K<sup>-</sup> < 5.5 mmol/L)
- Use cardiac monitoring if potassium levels normal or low

**Insulin**
- Critical, as this is the only way to inhibit gluconeogenesis/ketosis
- Do not give insulin if K<sup>-</sup> < 3.3 mmol/L
- Followed by continuous infusion at 5-10 U (or 0.1 U/kg) per h
- Once the blood glucose < 14 mmol/L, patient should receive their regular insulin SC injection and the infusion should be stopped in 1 h
- Add D5W to IV fluids when blood glucose < 15 mmol/L to prevent hypoglycemia
- Bicarbonate is not given unless patient is at risk of death or shock (typically pH < 7.0)

**Hyperosmolar Hyperglycemic State**
- State of extreme hyperglycemia (44-133.2 mmol/L) due to relative insulin deficiency, counter-regulatory hormones excess, gluconeogenesis, and dehydration (due to osmotic diuresis)
- Clinical feature
  - Often older, Type 2 DM patients with more co-morbid illnesses and larger fluid losses with symptoms evolving over days to weeks, fewer GI symptoms and more neurological deficits than DKA including: mental disturbances, coma, delirium, seizures
  - Polyuria, N/V
- Investigations
  - Blood work: CBC, electrolytes, Ca<sup>2+</sup>, Mg<sup>2+</sup>, PO<sub>4</sub><sup>-3</sup>, Cr, BUN, glucose, ketones, osmolality
  - Urine: glucose and ketones
  - ABG or VBG
  - Find underlying cause: ECG, CXR, blood and urine C&S
- Management
  - Rehydration with IV NS (total water deficit estimated at average 100 cc/kg body weight)
  - O₂, cardiac monitoring, frequent electrolyte, and glucose monitoring
  - Insulin is controversial
  - Identify and treat precipitating factors, if present (the 5 Is)

**Hypoglycemia**
- Characterized by Whipple’s triad: low plasma glucose, symptoms suggestive of hypoglycemia, prompt resolution of symptoms when glucose administered
- Clinical feature
  - Neuroglycopenic symptoms: headaches, confusion, seizures, coma
  - Autonomic symptoms: diaphoresis, nausea, hunger, tachycardia, palpitations
- History and physical exam
  - Last meal, known DM, prior similar episodes, drug therapy, and compliance
  - Liver/renal/endocrine/neoplastic disease
  - Depression, alcohol or drug use
- Management
  - IV access and rapid blood glucose measurement
  - D50W 50 mL IV push, glucose PO if mental status permits
  - If IV access not possible, glucagon 1-2 mg IM, repeat x 1 in 10-20 min
  - O₂, cardiac, frequent blood glucose monitoring
  - Thiamine 100 mg IM (if alcohol abuse is suspected)
  - Full meal as soon as mental status permits
  - If episode due to long-acting insulin, or sulfonylureas, watch for prolonged hypoglycemia due to long t1/2 (may require admission for monitoring)
  - Search for cause (common causes include exogenous insulin, alcohol, or sulfonylureas)

**4 Criteria for DKA Dx**
- Hyperglycemia
- Metabolic acidosis
- Hyperketonemia
- Ketonuria

**Signs and Symptoms of DKA**
- D: Diuresis, dehydration, drowsy, delirium, dizziness
- K: Kusmaul’s breathing, ketotic breath
- A: Abdominal pain, anorexia

**Precipitating Factors in DKA**
- The 5 Is
  - Infection
  - Ischemia
  - Infarction
  - Intoxication
  - Insulin missed

**Causes of Hypoglycemia**
- Most common: excessive insulin use in setting of poor PO intake
- Common: alcohol intoxication, sepsis, liver disease, oral anti-hyperglycemics
- Rare: insulinomas, hypopituitarism, adrenal insufficiency, med side effects

**Cerebral edema may occur if hyperosmolality is treated too aggressively**
**Electrolyte Disturbances**

- see Nephrology, NP7

**Table 20. Electrolyte Disturbances**

<table>
<thead>

<td>Acute (ionized Ca²⁺ &lt;0.7 mM) requires immediate treatment: IV calcium gluconate 1-2 g in 10-20 min followed by slow infusion</td>
<td>Prolonged QT interval can arise (leading to dysrhythmia as can upper airway obstruction)</td>
</tr>
</tbody>
</table>

**Hypertensive Emergencies**

**Hypertensive Emergency (Hypertensive Crisis)**

- definition: severe elevation of BP with evidence of end-organ damage (CNS, retinal, CVS, renal, GI)
- etiology
  - essential HTN, emotional exertion, pain, use of sympathomimetic drugs (cocaine, amphetamine, etc.), MAOI use with ingestion of tyramine-containing food (cheese, red wine, etc.), pheochromocytoma, pregnancy
- clinical feature
  - investigations
    - blood work: CBC, electrolytes, BUN, Cr
    - urinalysis
    - peripheral blood smear: to detect microangiopathic hemolytic anemia
    - CXR: if SOB or chest pain
    - ECG, troponins, CK: if chest pain
    - CT head: if neurological findings or severe headache
    - toxickology screen if sympathomimetic overdose suspected
- management
  - in general, strategy is to gradually and progressively reduce BP in 24-48 h
  - lower BP by 25% over the initial 60 min by initiating antihypertensive therapy (usually nitroprusside and labetalol)
  - if preeclampsia, immediately consult OB/GYN (see Obstetrics, OB24)
  - establish arterial line; transfer to ICU for further reduction in BP under monitored setting
  - in case of ischemic stroke: do no rapidly reduce BP; maintain BP >150/100 for 5 d
  - in case of aortic dissection: rapid reduction of sBP to 110-120 STAT (do not resuscitate with IV fluids)
  - in case of excessive catecholamines: avoid β-blockers (except labetalol)
  - in case of ACS: address ischemia initially, then BP
Hypertensive Urgency

- definition: severely elevated BP (usually sBP >180, dBP >110) with no evidence of end-organ damage
- most often caused by non-adherence to prescriptions
- treatment: re-initiate antihypertensive therapy, acute BP reduction not indicated
- goal: differentiate hypertensive emergencies from hypertensive urgencies

| Phentolamine             | 5-15 mg q5-15min   | 1-2 min         | 3-10 min          | Tachycardia, headache, flushing | Catecholamine excess (e.g. pheochromocytoma) |

*Hypotension may occur when using any of these agents

Acute Coronary Syndrome

- see Cardiology and Cardiac Surgery, C27
- definition: new onset of chest pain, or acute worsening of previous chest pain, or chest pain at rest with:
  - negative cardiac biomarkers and no ECG changes = Unstable angina (UA)
  - positive cardiac biomarkers (elevated troponin) and NSTEMI (or ECG changes without ST elevation)
  - positive cardiac biomarkers (elevated troponin) and ST segment elevation on ECG = STEMI
- investigations
  - ECG STAT (as soon as history suggests possible ACS), troponin (2-6 h after symptom onset), CXR (to rule out other causes of the patient’s presentation)
- management
  - stabilize: ABCs, oxygen, IV access, cardiac monitors, oximetry
  - ASA 162-325 mg chewed and swallowed
  - nitroglycerin 0.3 mg SL q5min x 3; IV only if persistent pain, CHF, or hypertensive
  - contraindications: hypotension, phosphodiesterase inhibitor use, right ventricular infarctions (1/3 of all inferior MIs)
• anticoagulation: choice of anticoagulation (unfractionated heparin, LMWH, or fondaparinux) and additional antiplatelet therapy (clopidogrel, ticagrelor, or prasugrel) depends on STEMI vs. NSTEMI and reperfusion strategy
  • early cardiology consult for reperfusion therapy
    • UA/NSTEMI: early coronary angiography recommended if high TIMI risk score
    • STEMI: primary percutaneous coronary intervention (within 90 min) preferred; thrombolitics if PCI unavailable within 120 min of medical contact, symptoms <12 h and no contraindications
  • atorvastatin 80 mg to stabilize plaques
  • β-blocker if no signs of CHF, hemodynamic compromise, bradycardia, or severe reactive airway disease
  • ACEI initiated within 24 h

Sepsis

• see Infectious Diseases, ID19 and Respiratory, R30
• definitions
  • sepsis: life-threatening organ dysfunction caused by a dysregulated host response to infection
  • organ dysfunction defined as a change in baseline SOFA score ≥2 points
  • septic shock: profound circulatory, cellular, and metabolic abnormalities with greater risk of mortality than with sepsis alone
  • require vasopressors to maintain MAP ≥65 mmHg
  • associated with serum lactate ≥2 mmol/L without hypovolemia
• management
  • early recognition of sepsis and investigations to locate source of infection
  • identify severe sepsis with lactate or evidence of tissue hypoperfusion
  • early “goal-directed” therapy: ensure adequate organ perfusion
  • treatment priorities:
    • ABCs, monitors, lines
    • aggressive fluid resuscitation; consider ventilatory and inotropic support
    • cultures, then early empiric appropriate antibiotics - consider broad spectrum and atypical coverage
  • source control - e.g. remove infected Foley or surgery for ischemic gut
  • monitor adequate resuscitation with vital signs, inferior vena cava on U/S, and serial measurement of serum lactate

Stroke and Transient Ischemic Attack

• see Neurology, N48
• definitions
  • stroke: sudden loss of brain function due to ischemia (87%) or hemorrhage (13%) with persistence of symptoms >24 h or neuroimaging evidence
  • TIA: transient episode of neurologic dysfunction from focal ischemia without acute infarction or neuroimaging evidence
• clinical feature

Table 23. Signs and Symptoms of Stroke

</tr>
</tbody>
</table>
Investigations
• CBC, electrolytes, blood glucose, coagulation studies ± cardiac biomarkers ± toxicology screen
• non-contrast CT head: look for hemorrhage, ischemia
• ECG ± echocardiogram: rule out AFib, acute MI as source of emboli
• other imaging: carotid Doppler, CTA, MRA as appropriate

Management
• ABCs; intubation with RSI if GCS ≤8, rapidly decreasing GCS, or inadequate airway protection reflexes
• thrombolysis: immediate assessment for eligibility; need acute onset, <4.5 h from drug administration time AND compatible physical findings AND normal CT with no bleed
• elevating head of bed if risk of elevated ICP, aspiration, or worsening cardiopulmonary status
• NPO, IV ± cardiac monitoring
  • judge fluid rate carefully to avoid overhydration (cerebral edema) as well as underhydration (underperfusion of the ischemic penumbra)
  • BP control: only treat severe HTN (sBP >200 mmHg, dBP >120 mmHg, mean arterial BP >140 mmHg) or HTN associated with hemorrhagic stroke transformation, cardiac ischemia, aortic dissection, or renal damage; use IV nitroprusside or labetalol
• glyceric control: keep fasting glucose <6.5% in acute phase (5 d)
• cerebral edema control: hyperventilation, mannitol to decrease ICP if necessary
• consult neurosurgery, neurology, medicine as indicated

Medications
• acute ischemic stroke: thrombolytics (rt-PA, e.g. alteplase) if within 4.5 h of symptom onset with no evidence of hemorrhage on CT scan
• antiplatelet agents: prevent recurrent stroke or stroke after TIAs, e.g. Aspirin* (1st line); clopidogrel, Aggrenox® (2nd line)
• anticoagulation: DVT prophylaxis if mobile; treat AFib if present
• follow-up for consideration of carotid endarterectomy, cardiovascular risk optimization

Otolaryngological Presentations and Emergencies

• see Otolaryngology, OT6
• ear symptoms: otalgia, aural fullness, otorrhea, hearing loss, tinnitus, vertigo, pruritis, fever
• risk factors for hearing loss: Q-tip use, hearing aids, headphones, occupational noise exposure

Dizziness and Vertigo
• distinguish four types of dizziness: vertigo (“room spinning”), lightheadedness (“disconnected from environment”), presyncope (“almost blacking out”), dysequilibrium (“unstable, off-balance”)
• broad differential and diverse management (see Family Medicine, FM25 and Otolaryngology, OT12)
• consider adverse drug events

Otalgia (see Otolaryngology, OT6)
• differential diagnosis
  • infections: acute otitis externa, acute otitis media, otitis media with effusion, mastoiditis, myringitis, malignant otitis externa in diabetics, herpes simplex/zoster, auricular cellulitis, external canal abscess, dental disease
  • others: trauma, temporomandibular joint dysfunction, neoplasm, foreign body, cerumen impactions, trigeminal neuralgia, granulomatosis with polyangiitis
• inspect for otorrhea, palpate outer ear/mastoid, otoscopic examination to look for bulging erythematous tympanic membrane, perforation, membrane retraction, infiltration, vesicles, ulcers, masses, lesions
• C&S of ear canal discharge, if present
• CT head if suspicion of mastoiditis, malignant otitis externa
• antibiotics/antifungals/antivirals for respective infections

Hearing Loss (see Otolaryngology, OT7)
• differentiate conductive vs. sensorineural hearing loss
• rule out sudden sensorineural hearing loss (SSNHL), a medical emergency requiring high dose steroids and urgent referral
• an elderly patient presenting with unilateral tinnitus or SNHL must be presumed to have an acoustic neuroma (vestibular schwannoma) until proven otherwise
• consider audiogram and referral to or follow-up with family physician

Absolute Exclusion Criteria for tPA
• Suspected subarachnoid hemorrhage
• Previous intracranial hemorrhage
• Cerebral infarct or severe HI within the past 3 mo
• BP >185 mmHg systolic, or >110 mmHg diastolic
• Bleeding diathesis
• Prolonged PT >15 s or INR >1.7
• Platelet count <100,000
• Heparin received within last 48 h
• Current use of thrombin inhibitors or direct factor Xa inhibitors
• Blood glucose <2.8 mmol/L (<50 mg/dL)
• Intracranial hemorrhage on CT or large volume infarct

Relative Exclusion Criteria for tPA
• Only minor or rapidly improving symptoms
• Pregnancy
• GI or urinary hemorrhage within the past 21 d
• Seizure at onset causing postictal impairments
Epistaxis

- see Otolaryngology, OT26
- 90% of nosebleeds stem from the anterior nasal septum (Kiesselbach's plexus located in Little's area)
- can be life-threatening

Etiology
- most cases of epistaxis are caused by trauma (digital, blunt, foreign bodies)
- other causes: barometric changes, nasal dryness, chemicals (cocaine, Otrivin*), or systemic disease (coagulopathies, HTN, etc.)

Investigations
- blood work: CBC, PT/PTT (as indicated)
- imaging: X-ray, CT as needed

Treatment
- goals of treatment: localize bleeding and achieve hemostasis
- first-aid: ABCs, clear clots by blowing nose or suctioning, lean forward, pinch cartilaginous portion of nose for 20 min twice
- assess blood loss: vitals, IV NS, cross match 2 units pRBC if significant
- if first aid measures fail twice, proceed to packing
- apply an anterior pack
  - clear nose of any clots
  - apply topical anesthesia/vasoconstrictors (lidocaine with epinephrine, cocaine, or soaked pledgets)
  - insert either a traditional Vaseline® gauze pack or a commercial nasal tampon or balloon
  - if bleeding stops, arrange follow-up in 48-72 h for reassessment and pack removal
  - if packing both nares, prophylactic anti-staphylococcal antibiotics to prevent sinusitis or toxic shock syndrome
  - if bleeding is not controlled with anterior pressure, cautery with silver nitrate can be performed if the site of bleeding is identified (only cauterize one side of the septum because if both are cauterized this can lead to septal perforation)
  - if suspect posterior bleed or anterior packing does not provide hemostasis, consult ENT for posterior packing and further evaluation
  - posterior packing requires monitoring; can cause significant vagal response and posterior bleeding source can lead to significant blood loss, therefore usually requires admission

Disposition
- discharge: discharged upon stabilization and appropriate follow-up; educate patients about prevention (e.g. humidifiers, saline spray, avoiding irritants, managing HTN)
- admission: severe cases of refractory bleeding, and most cases of posterior packing

Gynecologic/Urologic Emergencies

Vaginal Bleeding

- see Gynecology, GY9 and Obstetrics, OB13

Etiology
- pregnant patient
  - 1st/2nd trimester: ectopic pregnancy, abortion (threatened, incomplete, complete, missed, inevitable, septic), molar pregnancy, implantation bleeding, friable cervix (most common cause)
  - 2nd/3rd trimester: placenta previa, placental abruption, premature rupture of membranes, preterm labour
  - other: trauma, bleeding cervical polyp, passing of mucous plug
- postpartum
  - postpartum hemorrhage, uterine inversion, retained placental tissue, endometritis
- non-pregnant patients
  - structural (PALM- polyps, adenomyosis, leiomyoma, malignancies/hyperplasia)
  - non-structural (COEIN - coagulopathy, ovulatory, endometrial, iatrogenic, NYD)

History
- characterize bleeding (frequency, duration, number of pads/tampons, types of pads used, cyclicity)
- pain, if present (OPQRSTUV)
- menstrual history, sexual history, STI history, syncope/pre-syncope, malignancy history, family history, hematological history, cardiac history, abdo history
- details of pregnancy, including gush of fluid and fetal movement (>20 wk)
Physical Exam
- ABC (especially noting postural BP/HR and mucous membranes)
- abdominal examination (signs of peritoneal pathology, tenderness, distension, mass)
- speculum examination (NOT IF 2nd/3rd trimester bleeding; perform only if placenta previa has been ruled out with U/S)
  - look for active bleeding, trauma/anomaly, and cervical dilation
- bimanual examination (cervical motion tenderness, size of uterus, cervical length/dilatation
- sterile gloves and speculum if pregnant
- POCUS: rule in intra-uterine or ectopic pregnancy, check for free fluid in pelvis/RUQ/LUQ, consider assessment of fluid responsiveness (intra-hepatic IVC collapsibility, carotid flow measurement)

Investigations
- β-hCG test for all patients with childbearing potential
- CBC, blood and Rh type, quantitative β-hCG, PTT, INR
- type & cross if significant blood loss
- transvaginal U/S (rule out ectopic pregnancy and spontaneous abortion)
- abdominal U/S (rule out placenta previa, fetal demise, or retained products post-partum)

Management
- ABCs
- pulse oximeter and cardiac monitors if unstable
- Rh immune globulin (Rhogam®) for vaginal bleeding in pregnancy and Rh-negative mother
  - 1st/2nd trimester pregnancy
    - ectopic pregnancy: definitive treatment with surgery or methotrexate
    - intrauterine pregnancy, no concerns of coexistent ectopic: discharge patient with obstetrics follow-up
  - U/S indeterminate or β-hCG >1000-2000 IU: further workup and/or gynecology consult
  - abortions: if complete, discharge if stable; for all others, consult gynecology
  - 2nd/3rd trimester pregnancy
    - placenta previa or placental abruption: obstetrics consult for possible admission
  - postpartum
    - manage ABCs: start 2 large bore IV rapid infusion, type & cross 4 units of blood, consult OB/GYN immediately
    - non-pregnant
      - if unstable admit to gynecology for IV hormonal therapy, possible D&C
      - non-structural abnormalities
        - tranexamic acid to stabilize clots
        - medroxyprogesterone acetate 10 mg PO OD x 10d, warn patient of a withdrawal bleed
        - stable structural abnormalities (fibroids, polyps, endometrial thickening, adenomyosis), outpatient gynecology referral once stable

Disposition
- decision to admit or discharge should be based on the stability of the patient, as well as the nature of the underlying cause; consult OB/GYN for patients requiring admission
- if patient can be safely discharged, ensure follow-up with family physician or gynecologist
- instruct patient to return to ED for increased bleeding, presyncope

Nephrolithiasis (Renal Colic)

- see Urology, U18

Epidemiology and Risk Factors
- 10% of population (twice as common in males)
- recurrence 50% at 5 yr
- peak incidence 30-50 yr of age
- 75% of stones <5 mm pass spontaneously within 2 wk, larger stones may require consultation

Clinical Features
- urinary obstruction → upstream distention of ureter or collecting system → severe colicky pain
- may complain of pain at flank, groin, testes, or tip of penis
- writhing, N/V, hematuria (90% microscopic), diaphoresis, tachycardia, tachypnea
- occasionally symptoms of trigonal irritation (frequency, urgency)
- fever, chills, rigors in secondary pyelonephritis
- peritoneal findings/anterior abdominal tenderness usually absent

Differential Diagnosis of Renal Colic
- acute ureteric obstruction
- acute abdomen: biliary, bowel, pancreas, AAA
- urogynecological: ectopic pregnancy, torsion/rupture of ovarian cyst, testicular torsion
- pyelonephritis (fever, chills, pyuria, vomiting)
- radiculitis (L1): herpes zoster, nerve root compression

Investigations
- CBC: elevated WBC in presence of fever may support an infectious cause
- electrolytes, Cr, BUN to assess renal function
- U/A: R&M (WBCs, RBCs, crystals), C&S
- non-contrast spiral CT is the study of choice
- abdominal U/S may demonstrate stone(s), hydronephrosis (consider in females of childbearing age or if patient has another contraindication to CT scanning), debris in the collecting system, reduced cortical vascularity, abnormal renal parenchyma
- AXR will identify large radioopaque stones (calcium, struvite, and cystine stones) but may miss smaller stones, uric acid stones, or stones overlying bony structures; consider as an initial investigation in patients who have a history of radioopaque stones and similar episodes of acute flank pain (CT necessary if film is negative)
- strain all urine for stone analysis

Management
- analgesics: NSAIDs (usually ketorolac [Toradol®], preferable over opioids), antiemetics, IV fluids if indicated
- urology consult may be indicated, especially if stone >5 mm, or if patient has signs of obstruction or infection
- α-blocker (e.g. tamsulosin) may be helpful to increase stone passage in select cases

Disposition
- most patients can be discharged
- ensure patient is stable, has adequate analgesia, and able to tolerate oral medications
- may advise hydration and limitation of protein, sodium, oxalate, and alcohol intake

Ophthalmologic Emergencies

- see Ophthalmology, OP5

History and Physical Exam
- patient may complain of pain, tearing, itching, redness, photophobia, foreign body sensation, trauma
- mechanism of foreign body insertion – if high velocity injury suspected (welding, metal grinding, metal striking metal), must obtain orbital X-rays, U/S, or CT scan to exclude presence of intraocular metallic foreign body
- ask about sexual partners and exposure of eye(s) to bodily fluids (semen, urine, blood, vaginal fluids, saliva, etc.)
- visual acuity in both eyes, pupils, extraocular structures, fundoscopy, tonometry, slit lamp exam

Management of Ophthalmologic Foreign Body
- copious irrigation with saline for any foreign body
- remove foreign body under slit lamp exam with cotton swab or sterile needle
- antibiotic drops qid until healed
- patching may not improve healing or comfort – do not patch contact lens wearers
- limit use of topical anesthetic to examination only (the evidence for this is mixed; if uncertain, ask ophthalmology)
- consider tetanus prophylaxis
- ophthalmology consult if globe penetration suspected

Kidney Stones
- 80% Calcium oxalate
- 10% Struvite
- 10% Uric acid

Obstruction + Infection
- = Urological Emergency
- Urgent urology consult

Indications for Admission to Hospital
- Intractable pain
- Fever (suggests infection) or other evidence of pyelonephritis
- Single kidney with ureteral obstruction
- Bilateral obstructing stones
- Intractable vomiting
- Compromised renal function

Visual acuity is the “vital sign” of the eyes and should ALWAYS be assessed and documented in both eyes when a patient presents to the ER with an ophthalmologic complaint

</tr>
</tbody>
</table>

Contraindications to Pupil Dilation
- Shallow anterior chamber
- Iris-supported lens implant
- Potential neurological abnormality requiring pupillary evaluation
- Caution with CV disease – mydriatics can cause tachycardia

Other Ophthalmologic Emergencies
- Infectious: Red eye, endophthalmitis, hypopyon
- Trauma: Globe rupture, orbital blow-out fractures, corneal injuries, eyelid laceration, hyphema, lens dislocation, retrobulbar hemorraghe
- Painful vision loss: Acute iritis, corneal abrasion, globe rupture, lens dislocation, retrobulbar hemorrhage, optic neuritis, temporal arteritis, endophthalmitis, keratitis
- Painless vision loss: Central retinal vein occlusion, amaurosis fugax, occipital stroke

Dermatologic Emergencies

Rash Characteristics

A. Diffuse Rashes
- Staphylococcal Scalded Skin Syndrome (SSSS)
  - caused by an exotoxin from infecting strain of coagulase-positive S. aureus
  - mostly occurs in children
  - prodrome: fever, irritability, malaise, and skin tenderness
  - sudden onset of diffuse erythema: skin is red, warm, and very tender
  - flaccid bullae that are difficult to see, then desquamate in large sheets
- Steven-Johnson Syndrome (SJS) and Toxic Epidermal Necrolysis (TEN)
  - see Dermatology, D22
  - caused by drugs (e.g. phenytoin, sulfas, penicillins, and NSAIDs), bone marrow transplantation, and blood product transfusions
  - usually occurs in adults
  - diffuse erythema followed by necrosis
  - severe mucous membrane blistering
  - entire epidermis desquamation
  - high mortality (>50%)
- Toxic Shock Syndrome (TSS)
  - see Infectious Diseases, ID21
  - caused by superantigen from S. aureus or GAS activating T-cells and cytokines
  - patient often presents with onset of shock and multi-organ failure, fever
  - diffuse erythematous macular rash
  - at least 3 organ systems involved: CNS, respiratory, GI, muscular, mucous membranes, renal, liver, hematologic, and skin (necrotizing fasciitis, gangrene)
vesicobullous lesions
- Erythema Multiforme (EM)
  - immunologic reaction to herpes simplex
  - viral prodrome 1-14 d before rash
  - target lesion: central grey bulla or wheal surrounded by concentric rings of erythema and normal skin

B. Discrete Lesions
- pyoderma gangrenosum
  - often associated with IBD, rheumatoid conditions, leukemia, and monoclonal gammopathies.
  - often occurs in arms, hands, feet, or perineal region
  - usually begins as painless macule/vesicle/pustule/bulla on red/blue base sloughing, leaving a gangrenous ulcer
- disseminated gonococcal infection
  - see Dermatology, D32
  - fever, skin lesions (pustules/vesicles on erythematous base ~5 mm in diameter), arthritis (joint swelling and tenderness), and septic arthritis (in larger joints, such as knees, ankles, and elbows)
  - most commonly in gonococcus-positive women during menstruation or pregnancy
  - skin lesions usually appear in extremities and resolve quickly (<7 d)
- meningococcemia
  - flu-like symptoms of headache, myalgia, N/V
  - petechial, macular, or maculopapular lesions with grey vesicular centres
  - usually a few millimeters in size, but may become confluent and hemorrhagic
  - usually appear in extremities, but may appear anywhere
  - look for signs of meningeal irritation: positive jolt accentuation test, Brudzinski, Kernig

History and Physical Exam
- determine onset, course, and location of skin lesions
- fever, joint pain
- associated symptoms: CNS, respiratory, GU, GI, renal, liver, mucous membranes
- medications, sexual encounters, living environment, occupational exposures
- vitals, physical exam based on relevant history

Investigations
- immediate consultation if patient unstable
- case-dependent, consider: CBC, electrolytes, Cr, AST, ALT, ALP, blood culture, skin biopsy, serum immunoglobulin levels (serum IgE)

Management
- general: judicious IV fluids and electrolyte control, consider vasopressors if hypotensive, prevention of infection
- determine if admission and consult needed: dermatology or infectious diseases
- specific management is determined by etiology
  - SSSS, TSS, DGI, and meningococcemia
  - IV antibiotics
- EM, SJS, and TEN
  - stop precipitating medication
  - fluids
  - symptomatic treatment: antihistamines, antacids, topical corticosteroids, systemic corticosteroids (controversial), prophylactic oral acyclovir, consider IVIG, plasmapheresis
  - TEN: debride necrotic tissue

Disposition
- most cases will require urgent care and hospitalization
- SJS & TEN: early transfer to burn centre improves outcome
Heat Exhaustion and Heat Stroke

**Heat Exhaustion**
- Clinical features relate to loss of circulating volume caused by exposure to heat stress
- "Water depletion": heat exhaustion occurs if lost fluid not adequately replaced
- "Salt depletion": heat exhaustion occurs when losses replaced with hypotonic fluid

**Heat Stroke**
- Life-threatening emergency resulting from failure of normal compensatory heat-shedding mechanisms
- Divided into classical and exertional subtypes
- If patient does not respond relatively quickly to cooling treatments, consider other possible etiologies of hyperpyrexia (e.g., meningitis, thyroid storm, anticholinergic poisoning, delirium tremens, infections), adverse drug events (including drug interactions).

<table>
<thead>
<tr>
<th>Table 28. Heat Exhaustion vs. Heat Stroke</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>No coma or seizures</td>
</tr>
<tr>
<td>Dehydration (HR, orthostatic hypotension)</td>
</tr>
<tr>
<td>May have elevated AST, ALT</td>
</tr>
</tbody>
</table>

| **Treatment** | Rest in a cool environment IV NS if orthostatic hypotension; otherwise replace losses slowly PO | Cool body temperature with water mist (e.g., spray bottle) and standing fans Ice water immersion also effective; monitor body temperature closely to avoid hypothermic overshoot Secure airway because of seizure and aspiration risk Give fluid resuscitation if still hypotensive after above therapy Avoid β-agonists (e.g., epinephrine), peripheral vasoconstriction, and antipyretics (e.g., ASA) |

Hypothermia and Cold Injuries

**Hypothermia**
- Hypothermia is defined as a core temperature below 35°C, in which the body’s heat loss is greater than heat production
- Predisposing risk factors: ethanol use, homelessness, psychiatric disease, and older age (the elderly have increased risk due to decreased physiological reserve, chronic diseases, medication side effects, and social isolation)
- Treatment based on re-warming and supporting cardiorespiratory function
- Complications: coagulopathy, acidosis, ventricular dysrhythmias (VFib), asystole, volume, and electrolyte depletion
- Labs: CBC, electrolytes, ABG, serum glucose, Cr/BUN, Mg++, Ca++, amylase, coagulation profile
- Imaging: CXR (aspiration pneumonia, pulmonary edema are common)
- Monitors: ECG, rectal thermometer, Foley catheter, NG tube, monitor metabolic status frequently

<table>
<thead>
<tr>

</thead>
<tbody>
<tr>
<td><strong>Class</strong></td>
</tr>
<tr>
<td>Mild</td>
</tr>
<tr>
<td>Moderate</td>
</tr>
<tr>
<td>Severe</td>
</tr>
</tbody>
</table>

**Re-warming Options**
- Gentle fluid and electrolyte replacement in all (due to cold diuresis)
- Passive external re-warming
  - Suitable for most stable patients with core temperature >32.2°C
  - Involves covering patient with insulating blanket; body generates heat and re-warms through metabolic process, shivering

**Hypothermia and Cold Injuries**

**Hypothermia**
- Hypothermia is defined as a core temperature below 35°C, in which the body’s heat loss is greater than heat production
- Predisposing risk factors: ethanol use, homelessness, psychiatric disease, and older age (the elderly have increased risk due to decreased physiological reserve, chronic diseases, medication side effects, and social isolation)
- Treatment based on re-warming and supporting cardiorespiratory function
- Complications: coagulopathy, acidosis, ventricular dysrhythmias (VFib), asystole, volume, and electrolyte depletion
- Labs: CBC, electrolytes, ABG, serum glucose, Cr/BUN, Mg++, Ca++, amylase, coagulation profile
- Imaging: CXR (aspiration pneumonia, pulmonary edema are common)
- Monitors: ECG, rectal thermometer, Foley catheter, NG tube, monitor metabolic status frequently

**Hypothermia and Cold Injuries**

**Hypothermia**
- Hypothermia is defined as a core temperature below 35°C, in which the body’s heat loss is greater than heat production
- Predisposing risk factors: ethanol use, homelessness, psychiatric disease, and older age (the elderly have increased risk due to decreased physiological reserve, chronic diseases, medication side effects, and social isolation)
- Treatment based on re-warming and supporting cardiorespiratory function
- Complications: coagulopathy, acidosis, ventricular dysrhythmias (VFib), asystole, volume, and electrolyte depletion
- Labs: CBC, electrolytes, ABG, serum glucose, Cr/BUN, Mg++, Ca++, amylase, coagulation profile
- Imaging: CXR (aspiration pneumonia, pulmonary edema are common)
- Monitors: ECG, rectal thermometer, Foley catheter, NG tube, monitor metabolic status frequently

**Afterdrop Phenomenon**
- Warming of extremities causes vasodilation and movement of cool pooled blood from extremities to core, resulting in a drop in core temperature leading to cardiac arrest
• active external re-warming
  • involves use of warming blankets
  • beware of “afterdrop” phenomenon
  • safer when done in conjunction with active core re-warming

• active core re-warming
  • generally for patients with core temperature <32.2°C, and/or with cardiovascular instability
  • avoids “afterdrop” seen with AER alone
  • re-warm core by using
    • warmed humidified oxygen, IV fluids
    • peritoneal dialysis with warm fluids
    • gastric/colonic/pleural irrigation with warm fluids
    • external circulation (cardiopulmonary bypass machine) is most effective and fastest

Approach to Cardiac Arrest in the Hypothermic Patient
• do all procedures gently or may precipitate VFib
• check pulse and rhythm for at least 1 min; may have profound bradycardia
• if any pulse at all (even very slow) do NOT do CPR
• if in VFib try to defibrillate up to maximum 3 shocks if core temperature <30°C
• intubate if required, ventilate with warmed, humidified O₂
• medications (vasopressors, antidysrhythmics) may not be effective at low temperatures controversial;
  may try one dose
• focus of treatment is re-warming

FROSTBITE

Classification
• ice crystals form between cells
• classified according to depth – similar to burns (1st to 3rd degree)
• 1st degree
  • symptoms: initial paresthesia, pruritus
  • signs: erythema, edema, hyperemia, no blisters
• 2nd degree
  • symptoms: numbness
  • signs: blistering (clear), erythema, edema
• 3rd degree
  • symptoms: pain, burning, throbbing (on thawing); may be painless if severe
  • signs: hemorrhagic blisters, skin necrosis, edema, no movement
• 4th degree
  • extension into subcuticular, osseous, and muscle tissues

Management
• treat for hypothermia: O₂, IV fluids, maintenance of body warmth
• remove wet and constrictive clothing
• immerse in 40-42°C agitated water for 10-30 min (very painful; administer adequate analgesia)
• clean injured area and leave it open to air
• consider aspiration/debridement of blisters (controversial)
• debride skin
• tetanus prophylaxis
• consider penicillin G as frost bite injury has high risk of infection
• surgical intervention may be required to release restrictive eschars
• never allow a thawed area to re-chill/freeze

Burns

• see Plastic Surgery, PL18

Clinical Feature/Physical Exam Findings
• burn size
  • rule of nines; does not include 1st degree burns
• burn depth
  • superficial (1st degree): epidermis only (e.g. sunburn), painful and tender to palpation
  • superficial partial thickness (2nd degree): extends to epidermis and superficial dermis, blister formation occurs, very painful
  • deep partial thickness (2nd degree): involves hair follicles, sebaceous glands; skin is blistered, exposed dermis is white to yellow, absent sensation
  • full thickness (3rd degree): epidermis and all dermal layers; skin is pale, insensate, and charred or leathery
  • deep (4th degree): involvement of fat, muscle, even bone

Management
• remove noxious agent/stop burning process
• establish airway if needed (indicated with burns >40% BSA or smoke inhalation injury)
• resuscitation for 2nd and 3rd degree burns (after initiation of 2 large bore IVs)
• fluid boluses if unstable
  • Parkland Formula: Ringer's lactate 4 cc/kg/%BSA burned; give half in first 8 h, half in next 16 h;
    maintenance fluids are also required if patient cannot tolerate PO hydration
  • urine output is best measure of resuscitation, should be 40-50 cc/h or 0.5 cc/kg/h; avoid diuretics
• pain relief: continuous morphine infusion with breakthrough bolus
• investigations: CBC, electrolytes, U/A, CXR, ECG, ABG, carboxyhemoglobin
• burn wound care: prevent infection, clean/debride with mild soap and water, sterile dressings
• escharotomy or fasciectomy for circumferential burns (chest, extremities)
• topical antibiotics, burn victims are highly susceptible to infection (portal of entry with reduced
  immune function) – systemic antibiotics are often required
• tetanus prophylaxis if burn is deeper than superficial dermis

Disposition
• admit
  • 2nd degree burns >10% BSA, or any significant 3rd degree burns
  • 2nd degree burns on face, hands, feet, perineum, or across major joints
  • electrical, chemical burns, and inhalation injury
  • burn victims with chronic medical conditions or immunosuppressed patients

Inhalation Injury

Etiology
• carbon monoxide or cyanide poisoning
• direct thermal injury: limited to upper airway (above the vocal cords)
• smoke causes bronchospasm and edema from particulate matter and toxic inhalants (tissue asphyxiates,
  pulmonary irritants, systemic toxins)

History and Physical Exam
• risk factors: closed space fires, period of unconsciousness, noxious chemicals involved
• cherry red skin (unreliable, usually post-mortem finding)
• singed nasal hairs, soot on oral/nasal membranes, sooty sputum
• hoarseness, stridor, dyspnea
• decreased LOC, confusion
• PO2: normal but O2 saturation low suggests CO poisoning

Investigations
• measure carboxyhemoglobin levels, co-oximetry
• ABG
• CXR ± bronchoscopy

Management
• CO poisoning: 100% O2 ± hyperbaric O2 (controversial)
• direct thermal injury: humidified oxygen, early intubation, pulmonary toilet, bronchodilators, and
  mucolytics (N-acetylcysteine)

MAMMALIAN BITES
• see Plastic Surgery, PL11

History
• time and circumstances of bite, symptoms, allergies, tetanus immunization status, comorbid conditions,
  risk of rabies exposure/transmission, HIV/hepatitis risk (human bite)
• high morbidity associated with clenched fist injuries, “fight bites”

Physical Exam
• assess type of wound: abrasion, laceration, puncture, crush injury
• assess for direct tissue damage: skin, bone, tendon, neurovascular status

Investigations
• if bony injury or infection suspected, check for fracture and gas in tissue with x-rays
• get skull films in children with scalp bite wounds ± CT to rule out cranial perforation
• ultrasound may be helpful for identifying abscess formation as well as locating radiolucent foreign
  bodies in infected wounds

Initial Management
• wound cleaning and copious irrigation as soon as possible
• irrigate/debride puncture wounds if feasible, but not if sealed or very small openings; avoid
  hydrodissection along tissue planes
• debridement is important in crush injuries to reduce infection and optimize cosmetic and functional
  repair
• culture wound if signs of infection (erythema, necrosis, or pus); obtain anaerobic cultures if wound foul smelling, necrotizing, or abscess; notify lab that sample is from bite wound
• suturing
  ▪ vascular structures (i.e. face and scalp) are less likely to become infected, therefore consider suturing
  ▪ allow avascular structures (i.e. pretibial regions, hands, and feet) to heal by secondary intention
• tetanus immunization if >10 yr or incomplete primary series

**Prophylactic Antibiotics**
- types of infections resulting from bites: cellulitis, lymphangitis, abscesses, tenosynovitis, osteomyelitis, septic arthritis, sepsis, endocarditis, meningitis
- a 3-5 d course of antibiotics is recommended for all bite wounds to the hand and should be considered in other bites if any high-risk factors present
- dog and cat bites (pathogens: Pasteurella multocida, S. aureus, S. viridans)
  ▪ 10-50% of cat bites, 5% of dog bites become infected
  ▪ 1st line: amoxicillin + clavulanic acid
- human bites (pathogens: Eikenella corrodens, S. aureus, S. viridans, oral anaerobes)
  ▪ 1st line: amoxicillin + clavulanic acid
- rabies (see Infectious Diseases, ID18)
  ▪ reservoirs: warm-blooded animals except rodents, lagomorphs (e.g. rabbits)
  ▪ post-exposure vaccine is effective; treatment depends on local prevalence

**INSECT BITES**
- bee stings
  ▪ 5 types of reactions to stings (local, large local, systemic, toxic, unusual)
  ▪ history and physical exam key to diagnosis; no lab test will confirm
  ▪ investigations: CBC, electrolytes, BUN, Cr, glucose, ABGs, ECG
  ▪ ABC management, epinephrine 0.1 mg IV over 5 min if shock, antihistamines, cimetidine 300 mg IV/IM/PO, steroids, β-agonists for SOB/wheezing 3 mg in 5 mL NS via nebulizer, local site management
- West Nile virus (see Infectious Diseases, ID22)

---

**Near Drowning**

• most common in children <4 yr and teenagers
• causes lung damage, hypoxemia, and may lead to hypoxic encephalopathy
• must also assess for shock, C-spine injuries, hypothermia, and scuba-related injuries (barotrauma, air emboli, lung re-expansion injury)
• complications: volume shifts, electrolyte abnormalities, hemolysis, rhabdomyolysis, renal, DIC

**Physical Exam**
- ABCs, vitals: watch closely for hypotension
- respiratory: rales (ARDS, pulmonary edema), decreased breath sounds (pneumothorax)
- CVS: murmurs, dysrhythmias, JVP (CHF, pneumothorax)
- H&N: assess for C-spine injuries
- neurological: GCS or AVPU, pupils, focal deficits

**Investigations**
- labs: CBC, electrolytes, ABGs, Cr, BUN, INR, PTT, U/A (drug screen, myoglobin)
- imaging: CXR (pulmonary edema, pneumothorax) ± C-spine imaging
- ECG

**Management**
- ABCs, treat for trauma, shock, hypothermia
- cardiac and O2 monitors, IV access
- intensive respiratory care
  ▪ ventilator assistance if decreased respirations, pCO2 >50 mmHg, or pO2 <60 mmHg on maximum O2
  ▪ may require intubation for airway protection, ventilation, pulmonary toilet
  ▪ high flow O2/CPAP/BiPAP may be adequate but some may need mechanical ventilation with positive end-expiratory pressure
  ▪ dysrhythmias: usually respond to corrections of hypoxemia, hyperthermia, and acidosis
  ▪ vomiting: very common, NG suction to avoid aspiration
  ▪ convulsions: usually respond to O2; if not, diazepam 5-10 mg IV slowly
  ▪ bronchospasm: bronchodilators
  ▪ bacterial pneumonia: prophylactic antibiotics not necessary unless contaminated water or hot tub (Pseudomonas)
  ▪ always initiate CPR in drowning-induced cardiac arrest even if patient hypothermic; continue CPR until patient is fully rewarmed

**Disposition**
- non-significant submersion: discharge after short observation
- significant submersion (even if asymptomatic): long period of observation (72 h) as pulmonary edema may appear late
- CNS symptoms or hypoxemia: admit
- severe hypoxemia, decreased LOC: ICU

*Secondary drowning* where the onset of symptoms, as a result of pulmonary edema or infection, can be insidious, developing over hours, or possibly even days, must be anticipated in the near drowning patient.
Toxicology

"ABCD3EFG" of Toxicology

- basic axiom of care is symptomatic and supportive treatment
- address underlying problem only once patient is stable

A  Airway (consider stabilizing C-spine)
B  Breathing
C  Circulation
D1  Drugs
   - ACLS as necessary to resuscitate the patient
   - universal antidotes
D2  Draw bloods
D3  Decontamination (decrease absorption)
E  Expose (look for specific toxidromes)/Examine the patient
F  Full vitals, ECG monitor, Foley, X-rays
G  Give specific antidotes and treatments

- reassess
- call Poison Information Centre
- obtain corroborative history from family, bystanders

D1 – Universal Antidotes

- treatments that will not harm patients and may be essential

Dextrose (glucose)
- give to any patient presenting with altered LOC
- measure blood glucose prior to glucose administration if possible
- adults: 0.5-1.0 g/kg (1-2 mL/kg) IV of D50W
- children: 0.25 g/kg (2-4 mL/kg) IV of D25W

Oxygen
- do not deprive a hypoxic patient of oxygen no matter what the antecedent medical history (i.e. even COPD with CO2 retention)
- if depression of hypoxic drive, intubate and ventilate
- exception: paraquat or diquat (herbicides) inhalation or ingestion (oxygen radicals increase morbidity)

Naloxone (central µ-receptor competitive antagonist, shorter t1/2 than naltrexone)
- antidote for opioids: administration is both diagnostic and therapeutic (1 min onset of action)
- used for the undifferentiated comatose patient
- loading dose
  - adults
    - response to naloxone can be drastic, so stepwise delivery of initial 2 mg bolus is recommended
    - draw up 2 mg to deliver IV/IM/SL/SC or via ETT (ETT dose = 2-2.5x IV dose)
      - 1st dose 0.4 mg (for a chronic opioid user, the initial dose may be much smaller)
      - if no response, deliver second dose 0.6 mg
      - if still no response, deliver remaining 1 mg
  - child
    - 0.01 mg/kg initial bolus IV/IO/ETT (max 2mg per dose)
    - children over 20 kg can receive naloxone 2 mg IV
- maintenance dose
  - may be required because half-life of naloxone (30-80 min) is much shorter than many opioids
  - hourly infusion rate at 2/3 of initial dose that allowed patient to be roused

Thiamine (Vitamin B1)
- 100 mg IV/IM with IV/PO glucose to all patients
- given to prevent/treat Wernicke's encephalopathy
- a necessary cofactor for glucose metabolism (may worsen Wernicke's encephalopathy if glucose given before thiamine), but do not delay glucose if thiamine unavailable
- must assume all undifferentiated comatose patients are at risk
D2 – Draw Bloods

- essential tests
  - CBC, electrolytes, BUN/Cr, glucose, INR/PTT, osmolality
  - ABGs, O₂ sat
  - ASA, acetaminophen, EtOH levels
- potentially useful tests
  - drug levels – this is NOT a serum drug screen
  - Ca²⁺, Mg²⁺, PO₄³⁻
  - protein, albumin, lactate, ketones, liver enzymes, CK – depending on drug and clinical feature

Serum Drug Levels

- treat the patient, not the drug level
- negative toxicology screen does not rule out a toxic ingestion – signifies only that the specific drugs tested were not detectable in the specimen
- specific drugs available on general screen vary by institution; check before ordering
- urine screens also available (qualitative only; not often thought to change management)

Table 30. Toxic Gaps (see Nephrology, NP16)

<table>
<thead>
<tr>
<th>Metabolic Acidosis</th>
<th>Increased osmolar gap: “MAE DIE” (if it ends in “-ol”, it will likely increase the osmolar gap)</th>

</tbody>
</table>
**D3 – Decontamination and Enhanced Elimination**

**Ocular Decontamination**
- saline irrigation to neutralize pH; alkali exposure requires ophthalmology consult

**Dermal Decontamination (Wear Protective Gear)**
- remove clothing, brush off toxic agents, irrigate all external surfaces

**Gastrointestinal Decontamination**
- single dose activated charcoal
  - use of activated charcoal is a source of much debate amongst toxicologists. Evidence of effectiveness is not strong, and risk of aspiration is high.
  - adsorption of drug/toxin to activated charcoal decreases toxin bioavailability
  - contraindications: unprotected airway, late presentation after ingestion, small bowel obstruction, poor toxin adsorption
  - dose: 10 g/g drug ingested or 1g/kg body weight (may vary depending on ingestion)
  - odourless, tasteless, prepared as slurry with H₂O
- whole bowel irrigation (very rarely used)
  - 500 mL/h (child) to 2000 mL/h (adult) of polyethylene glycol solution by mouth until clear effluent per rectum
  - start slow (500 mL in an adult) and aim to increase rate hourly as tolerated
  - indications
    - awake, alert, can be nursed upright OR intubated and airway protected
    - delayed release product
    - drug/toxin not bound to charcoal
    - drug packages (if any evidence of breakage emergency surgery)
    - recent toxin ingestion
  - contraindications
    - evidence of ileus, perforation, or obstruction
- multidose activated charcoal
  - may be used for: carbamazepine, phenobarbital, quinine, theophylline for toxins which undergo enterohepatic recirculation
  - removes drug that has already been absorbed by drawing it back into GI tract
  - various regimens: 12.5 g (1/4 bottle) PO q1h or 25 g (1/2 bottle) PO q2h until non-toxic
  - surgical removal in extreme cases
    - surgical indicated for drugs that are toxic, form concretions, or cannot be removed by conventional means
  - use of cathartics (i.e. ipecac) and gastric lavage in the ED is not recommended

**Lipid Emulsification**
- new therapy used in cardiogenic shock due to toxins
  - may be used for: anesthetics, β-blocker and calcium channel blocker overdose
  - initial bolus 1.5mL/kg 20% lipid solution over 2-3 min then infusion of 0.25mL/kg/min

**Urine Alkalinization**
- may be used for: ASA, methotrexate, phenobarbital, chlorpropamide
  - weakly acidic substances can be trapped in alkali urine (pH >7.5) to increase elimination

**Hemodialysis**
- indications/criteria for hemodialysis
  - toxins that have high water solubility, low protein binding, low molecular weight, adequate concentration gradient, small volume of distribution, or rapid plasma equilibration
  - clinical deterioration despite maximal medical support
- useful for the following toxins
  - methanol
  - ethylene glycol
  - salicylates
  - lithium
  - phenobarbital
  - chloral hydrate (trichloroethanol)
- others include theophylline, carbamazepine, valproate, methotrexate
E – Expose and Examine the Patient

- vital signs (including temperature), skin (needle tracks, colour), mucous membranes, pupils, odours, and CNS
- head-to-toe survey including
  - C-spine
  - signs of trauma, seizures (incontinence, “tongue biting”, etc.), infection (meningismus), or chronic alcohol/drug misuse (track marks, nasal septum erosion)
  - feel the patient's axillae; in the average patient, should be somewhat moist (if dry, may indicate anticholinergic toxicity)
- mental status

</table>

Note: ASA poisoning and hypoglycemia mimic sympathomimetic toxidrome

F – Full Vitals, ECG Monitor, Foley, X-Rays

G – Give Specific Antidotes and Treatments

Urine Alkalinization Treatment for ASA Overdose
- urine pH > 7.5
- fluid resuscitate first, then 3 amps NaHCO₃/L of D5W at 1.5x maintenance
- add 20-40 mEq/L KCl if patient is able to urinate
### Table 33. Protocol for Warfarin Overdose

<table>
<thead>
<tr>
<th>INR</th>
<th>Management</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;0.5</td>
<td>Cessation of warfarin administration, observation, serial INR/PT</td>
</tr>
<tr>
<td>5.1–9.0</td>
<td>If no risk factors for bleeding, hold warfarin x 1-2 d and reduce maintenance dose OR Vitamin K 1-2 mg PO if patient at increased risk of bleeding</td>
</tr>
<tr>
<td>9.1–20.0</td>
<td>Hold warfarin, vitamin K 2-4 mg PO, serial INR/PT, additional vitamin K if necessary</td>
</tr>
<tr>
<td>&gt;20.0</td>
<td>Hold warfarin, vitamin K 10 mg IV over 10 min, increase vitamin K dosing (q4h) if needed</td>
</tr>
</tbody>
</table>

### Table 34. Specific Antidotes and Treatments for Common Toxins*

<table>
<thead>
<tr>
<th>Toxin</th>
<th>Treatment</th>
<th>Considerations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Acetaminophen</td>
<td>Decontaminate (activated charcoal) N-acetylcysteine</td>
<td>Often clinically silent; evidence of liver/renal damage delayed &gt;24 h</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Monitor drug level 4 h post-ingestion; also liver enzymes, INR, PTT, BUN, Cr</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Hypoglycemia, metabolic acidosis, encephalopathy poor prognosis</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Dialysis may be required to manage in very high overdoses</td>
</tr>
<tr>
<td>Acute Dystonic Reaction</td>
<td>Benztropine: 1-2 mg IM/IV then 2 mg PO x 3 d OR Diphenhydramine 1-2 mg/kg IV, then 25 mg PO qid x 3 d</td>
<td>Benztropine (Cogentin®) has euphoric effect and the potential for misuse</td>
</tr>
<tr>
<td>Anticholinergics</td>
<td>Consider decontamination (activated charcoal) Supportive care</td>
<td>Special antidotes available; consult Poison Information Centre</td>
</tr>
<tr>
<td>ASA</td>
<td>Consider decontamination (activated charcoal) Alkalize urine; want urine pH &gt;7.5</td>
<td>Monitor serum pH and drug levels closely</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Monitor K⁺ level; may require supplement for urine alkalinization</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Hemodialysis may be needed if intractable metabolic acidosis, very high levels, or end-organ damage (i.e. unable to diurese)</td>
</tr>
<tr>
<td>Benzodiazepines</td>
<td>Consider decontamination (activated charcoal) Flumazenil Supportive care</td>
<td></td>
</tr>
<tr>
<td>β-blockers</td>
<td>Consider decontamination (activated charcoal), consider whole bowel irrigation for extended-release ingestion) IV glucagon, IV calcium chloride, IV high-dose insulin (with dextrose), IV intralipid</td>
<td></td>
</tr>
<tr>
<td>Calcium Channel Blockers</td>
<td>Consider decontamination (activated charcoal), consider whole bowel irrigation for extended-release ingestion) IV glucagon, IV calcium chloride, IV high-dose insulin (with dextrose), IV intralipid</td>
<td>Order ECG, electrolytes (especially Ca²⁺, Mg²⁺, Na⁺, K⁺)</td>
</tr>
<tr>
<td>Cocaine</td>
<td>Decontaminate (activated charcoal) if oral Aggressive supportive care</td>
<td>β-blockers are contraindicated in acute cocaine toxicity</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Intralipid for life-threatening symptoms</td>
</tr>
<tr>
<td>CO Poisoning</td>
<td>See Inhalation Injury, ER47 Supportive care 100% O₂; may require hyperbaric O₂</td>
<td>Order ECG, VBG. Consider lactate and troponin depending on specific presentation</td>
</tr>
<tr>
<td>Cyanide</td>
<td>Hydroxocobalamin</td>
<td></td>
</tr>
<tr>
<td>Digoxin</td>
<td>Consider decontamination (activated charcoal) Digoxin-specific Ab fragments 10-20 vials IV if acute; 3-6 if chronic 1 vial (40 mg) neutralizes 0.5 mg of toxin</td>
<td>Use for life-threatening dysrhythmias unresponsive to conventional therapy, 6 h serum digoxin &gt;12 nmol/L, initial K⁺ &gt;5 mmol/L ingestion &gt;10 mg (adult)/&gt;4 mg (child) Common dysrhythmias include VFib, VTach, and conduction blocks</td>
</tr>
<tr>
<td>Ethanol</td>
<td>Thiamine 100 mg IM/IV Manage airway and circulatory support</td>
<td>Mouthwash = 70% EtOH; perfumes and colognes = 40-60% EtOH Order serum EtOH level and glucose level; treat glucose level appropriately</td>
</tr>
<tr>
<td>Ethylene Glycol/ Methanol</td>
<td>Fomepizole (4-methylpyrazole) 15 mg/kg IV load over 30 min, then 10 mg/kg q12h OR Ethanol (10%) 10 mL/kg over 30 min, then 1.5 mL/h</td>
<td>CBC, electrolytes, glucose, ethanol level Consider hemodialysis</td>
</tr>
<tr>
<td>Heparin</td>
<td>Protamine sulfate 25-50 mg IV</td>
<td>For unfractionated heparin overdose only</td>
</tr>
<tr>
<td>Insulin IM/SC/ Oral Hypoglycemic</td>
<td>Glucose IV/P/ONS tube Glucagon: 1-2 mg IM (if no access to glucose)</td>
<td>Glyburide carries highest risk of hypoglycemia among oral agents Consider octreotide for oral hypoglycemics (50-100 µg SC q8h) in these cases; consult local Poison Information Centre</td>
</tr>
<tr>
<td>MDMA</td>
<td>Consider decontamination (activated charcoal) Supportive care</td>
<td>Monitor CK; treat rhabdomyolysis with high flow fluids: aggressive external cooling for hyperthermia Review medical history if possible for serotonergic use</td>
</tr>
<tr>
<td>Opioids</td>
<td>See Universal Antidotes, ER49</td>
<td></td>
</tr>
<tr>
<td>TCAs</td>
<td>Consider decontamination (activated charcoal) Aggressive supportive care NaHCO₃ bolus for wide ORS/seizures Flumazenil antidote contraindicated in combined TCA and benzodiazepine overdose Also consider cardiac and hypotension support, seizure control Intralipid therapy</td>
<td></td>
</tr>
</tbody>
</table>

* Call local Poison Information Centre for reporting of cases, specific doses, and treatment recommendations. Most toxicology cases should involve communication with your local Poison Information Centre.
Alcohol Related Emergencies

- see Psychiatry PS26

**Acute Intoxication**
- slurred speech, CNS depression, disinhibition, lack of coordination
- nystagmus, diplopia, dysarthria, ataxia, may progress to coma
- hypotension (peripheral vasodilation)
- if obtunded, rule out
  - head trauma/intracranial hemorrhage
  - associated depressants, toxic alcohols
- may also contribute to respiratory/cardiac depression
  - hypoglycemia (screen with bedside glucometer)
  - hepatic encephalopathy: confusion, altered LOC, coma
- precipitating factors: GI bleed, infection, sedation, electrolyte abnormalities, protein meal
  - Wernicke's encephalopathy (ataxia, ophthalmoplegia, delirium)
  - post-ictal state, basilar stroke

**Withdrawal**
- beware of withdrawal signs
- treatment
  - diazepam 10-20 mg IV/PO or lorazepam 2-4 mg IV/PO q1h until calm
- frequency of dosing may have to be increased depending on clinical response
  - may use CIWA protocol and give benzodiazepines as above until CIWA <10
  - thiamine 100 mg IM/IV then 50-100 mg/d
  - magnesium sulfate 4 g IV over 1-2 h (if hypomagnesemic)
  - admit patients with delirium tremens or multiple seizures

<table>
<thead>
<tr>
<th>Time Since Last Drink</th>
<th>Syndrome</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6-8 h</td>
<td>Mild withdrawal</td>
<td>Generalized tremor, anxiety, agitation, but no delirium Autonomic hyperactivity (sinus tachycardia), insomnia, N/V</td>
</tr>
<tr>
<td>1-2 d</td>
<td>Alcoholic hallucinations</td>
<td>Visual (most common), auditory, and tactile hallucinations Vitals often normal</td>
</tr>
<tr>
<td>8 h-2 d</td>
<td>Withdrawal seizures</td>
<td>Typically brief generalized tonic-clonic seizures May have several within a few hours CT head if focal seizures have occurred</td>
</tr>
<tr>
<td>3-5 d</td>
<td>DT</td>
<td>5% of untreated withdrawal patients Severely confused state, fluctuating LOC Agitation, insomnia, hallucinations/delusions, tremor Tachycardia, hyperpyrexia, diaphoresis High mortality rate</td>
</tr>
</tbody>
</table>

**Cardiovascular Complications**
- HTN
- cardiomyopathy: SOB, edema
- dysrhythmias (“holiday heart”)
- AFib (most common), atrial flutter, SVT, VTach (especially Torsades if hypomagnesemic/hypokalemic)

**Metabolic Abnormalities**
- alcoholic ketoacidosis
  - antigen metabolic acidosis, urine ketones, low glucose, and normal osmolality
  - history of chronic alcohol intake with abrupt decrease/cessation
  - malnourished, abdominal pain with N/V
  - treatment: dextrose, thiamine (100 mg IM/IV prior to dextrose), volume repletion (with NS)
  - generally resolves in 12-24 h
- other alcohols
  - ethylene glycol: CNS, CVS, renal findings
  - methanol
    - early: lethargy, confusion
    - late: headache, visual changes, N/V, abdominal pain, tachypnea
  - both ethylene glycol and methanol produce severe metabolic acidosis with anion gap (as the alcohol is metabolized) and osmolar gap (initially after ingestion but before metabolism)
  - EtOH co-ingestion is protective
- treatment
  - urgent hemodialysis required
  - fomepizole 15 mg/kg IV bolus (treatment of choice) or EtOH 10% IV bolus and infusion to achieve blood level of 22 mmol/L (EtOH loading may be done PO)
  - consider folic acid for methanol, and pyridoxine and thiamine for ethylene glycol – both help reduce conversion to active metabolites
- other abnormalities associated with alcohol: hypomagnesemia, hypophosphatemia, hypocalcemia, hypoglycemia, hypokalemia

**Gastrointestinal Abnormalities**
- gastritis
  - common cause of abdominal pain and GI bleed in chronic alcohol users
- pancreatitis
  - serum amylase very unreliable in patients with chronic pancreatitis, may need serum lipase
  - hemorrhagic form (15%) associated with increased mortality
  - fluid resuscitation very important
- hepatitis
  - AST/ALT ratio >2 suggests alcohol as the cause as well as elevated GGT with acute ingestion
- peritonitis/spontaneous bacterial peritonitis
  - leukocytosis, fever, generalized abdominal pain/tenderness
  - occasionally accompanies cirrhosis
  - paracentesis for diagnosis (common pathogens: E. coli, Klebsiella, Streptococcus)
  - albumin shown to improve outcomes in SBP patients
- GI bleeds
  - most commonly gastritis or ulcers, even if patient known to have varices
  - consider Mallory-Weiss tear secondary to retching
  - often complicated by underlying coagulopathies
  - minor: treat with antacids
  - severe or recurrent: endoscopy

**Disposition**
- before patient leaves ED ensure stable vital signs, can walk unassisted, and fully oriented
- offer social services to find shelter or detox program
- ensure patient can obtain any medications prescribed and can complete any necessary follow-up

## Approach to the Overdose Patient

### History
- age, weight, underlying medical problems, medications
- substance, route, and quantity
- time and symptoms since exposure determines prognosis and need for decontamination
- route
- intention, suicidality

### Physical Exam
- focus on: ABCs, LOC/GCS, vitals, pupils

### Disposition from the Emergency Department
- methanol, ethylene glycol
  - delayed onset, admit, and watch clinical and biochemical markers
- TCAs
  - prolonged/delayed cardiotoxicity warrants admission to monitored ICU bed
  - if asymptomatic and no clinical signs of intoxication: 6 h ED observation adequate with proper decontamination and no ECG abnormalities
  - sinus tachycardia alone (most common finding) with history of overdose warrants observation in ED
- hydrocarbons/smoke inhalation
  - pneumonitis may lag 6-8 h
  - consider observation for repeated clinical and radiographic examination
- ASA, acetaminophen
  - if borderline level, get second level 2-4 h after first
  - for ASA, must have at least 2 measurements showing decreasing toxin serum concentration before discharge (3 levels minimum)
- oral hypoglycemics
  - admit all patients for minimum 24 h if hypoglycemic and 12 h after last octreotide dose
  - observe asymptomatic patient for at least 8 h

### Psychiatric Consultation
- once patient medically cleared, arrange psychiatric intervention if required
- beware – suicidal ideation may not be expressed
Psychiatric Emergencies

Approach to Common Psychiatric Presentations

- see Psychiatry, PS2
- before seeing patient, ensure your own safety; have security/police available if necessary

History
- safety
  - assess suicidality: suicidal ideation (SI), intent, plan, lethal means, past attempts, protective factors
  - assess homicidality: homicidal ideation (HI), access to weapons, intended victim, and history of violence
  - driving and children
  - command hallucinations
- identify current stressors and coping strategies
- mood symptoms: manic, depressive
- anxiety: panic attacks, generalized anxiety, phobias, obsessive-compulsive disorder, post-traumatic stress disorder
- psychotic symptoms: delusions, hallucinations, disorganized speech, disorganized or catatonic behaviour, negative symptoms (affective flattening, alogia, avolition)
- substance use history: most recent use, amount, previous withdrawal reactions
- past psychiatric history, medications, adherence with medications
- medical history: obtain collateral if available

Physical Exam
- complete physical exam focusing on: vitals, neurological exam, signs of head trauma, signs of drug toxicity, signs of metabolic disorder
- mental status exam: general appearance, behaviour, cooperation, speech, mood and affect, thought content and form, perceptual disturbances, cognition (including MMSE if indicated), judgment, insight, reliability

Investigations
- investigations vary with age, established psychiatric diagnosis vs. first presentation, history and physical suggestive of organic cause
  - as indicated: blood glucose, urine and serum toxicology screen, pregnancy test, electrolytes, TSH, AST/ALT, bilirubin, serum Cr, BUN, and osmolality
  - blood levels of psychiatric medications
  - CT head if suspect neurological etiology
  - LP if indicated

Acute Psychosis

Differential Diagnosis
- primary psychotic disorder (e.g. schizophrenia)
- secondary to medical condition (e.g. delirium)
- drugs: substance intoxication or withdrawal, medications (e.g. steroids, anticholinergics)
- infectious (CNS)
- metabolic (hypoglycemic, hepatic, renal, thyroid)
- structural (hemorrhage, neoplasm)

Management
- violence prevention
  - remain calm, empathic, and reassuring
  - ensure safety of staff and patients, have extra staff and/or security on hand
  - patients demonstrating escalating agitation or overt violent behaviour may require physical restraint and/or chemical restraint
  - treat agitation: whenever possible, offer medication to patients as opposed to administering with force (helps calm and engage patient)
    - benzodiazepines: lorazepam 2 mg PO/IM/SL
    - antipsychotics: olanzapine 5 mg PO, haloperidol 5 mg PO/IM
  - treat underlying medical condition
  - psychiatry or Crisis Intervention Team consult

Key Functions of Emergency Psychiatric Assessment
- Is the patient medically stable?
- Rule out medical cause
- Is psychiatric consult needed?
- Are there safety issues (SI, HI)?
- Is patient certifiable? Must demonstrate risk (present/past test) and apparent mental illness (future test)

Psychiatric Review of Systems

MOAPS
M - Mood
O - Organic
A - Anxiety
P - Psychosis
S - Safety
Suicidal Patient

Epidemiology
• attempted suicide F>M, completed suicide M>F
• second leading cause of death in people <24 yr
• risk is significantly increased in indigenous and LGBTQ Canadians, particularly trans individuals

Management
• ensure patient safety; close observation, remove potentially dangerous objects from person and room
• assess thoughts (ideation), means, action (preparatory, practice attempts), previous attempts, protective factors
• admit if there is evidence of active intent and organized plan, access to lethal means, psychiatric disorder, intoxication (suicidal ideation may resolve with few days of abstinence)
• patient may require certification if unwilling to stay voluntarily
• do not start long-term medications in the ED
• psychiatry or Crisis Intervention Team consult

Respiratory Distress

- see Pediatrics, P70

History and Physical Exam
• infants not able to feed, older children not able to speak in full sentences
• anxious, irritable, lethargic – may indicate hypoxia
• tachypnea >60 (>40 if preschool age, >30 if school age), retractions, tracheal tug
- see Pediatrics, P3 for age specific vital signs
• pulsus paradoxus
• wheezing, grunting, vomiting

†Now rare with Hib vaccine in common use
Management
- **croup** (usually laryngotracheitis caused by parainfluenza viruses)
  - dexamethasone x 1 dose
  - if moderate-severe, add nebulized epinephrine (racemic has limited availability)
  - consider bacterial tracheitis/epiglottitis if unresponsive to croup therapy
  - humidified O₂ has no evidence for efficacy
- **bacterial tracheitis**
  - airway maintenance - usually require intubation, ENT consult, ICU
  - start antibiotics (e.g. cloxacillin), pending C&S
- **epiglottitis**
  - 4 Ds: drooling, dyspnea, dysphagia, dysphonia + tripod sitting
  - do not examine oropharynx or agitate patient
  - immediate anesthesia, ENT call – intubate
  - then IV fluids, antibiotics, blood cultures
- **asthma**
  - supplemental O₂ if saturation <90% or PaO₂ <60%
  - bronchodilator therapy: salbutamol (Ventolin®) 0.15 mg/kg x3 by masks q20min
  - give corticosteroid therapy as soon as possible after arrival (prednisolone 2 mg/kg, dexamethasone 0.6 mg/kg, 2 doses 24 h apart)
  - if severe, add 250-500 µg ipratropium (Atrovent®) to first 3 doses salbutamol if critically ill, not responding to inhaled bronchodilators or steroids: give IV bolus, then infusion of MgSO₄
  - IV β₂-agonists if critically ill and not responding to above

**Febrile Infant and Febrile Seizures**

**FEVERLE INFANT**
- for fever >38°C without obvious focus
  - <28 d
    - admit
    - full septic workup (CBC and differential, blood C&S, urine C&S, LP ± stool C&S, CXR if indicated)
    - treat empirically with broad spectrum IV antibiotics
  - 28-90 d
    - as above unless infant meets Rochester criteria, partial septic workup (CBC and differential, blood C&S, urine C&S, CXR if indicated)
  - >90 d
    - toxic: admit, treat, full septic workup
    - non-toxic and no focus: investigate as indicated by history and physical

**FEVERLE SEIZURES**
- see Pediatrics, P78

**Etiology**
- children aged 6 mo-6 yr with fever or history of recent fever
- typical vs. atypical febrile seizures
- normal neurological exam afterward
- no evidence of intracranial infection or history of previous non-febrile seizures
- often positive family history of febrile seizures
- relatively well-looking after seizure

**Investigations and Management**
- if confirmed febrile seizure: treat fever and look for source of fever
- if not a febrile seizure: treat seizure and look for source of seizure
  - note: may also have fever but may not meet criteria for febrile seizure
  - ± EEG (especially if first seizure), head U/S (if fontanelle open)

**Child Abuse and Neglect**

- see *Pediatrics*, P15
- obligation to report any suspected/known case of child abuse or neglect to CAS yourself (do not delegate)
- document injuries
- consider skeletal survey x-rays (especially in non-ambulatory child), ophthalmology consult, CT head
- injury patterns associated with child abuse
  - HI: torn frenulum, dental injuries, bilateral black eyes, traumatic hair loss, diffuse severe CNS injury, retinal hemorrhage
  - Shaken Baby Syndrome: diffuse brain injury, subdural/SAH, retinal hemorrhage, minimal/no evidence of external trauma, associated bony fractures
  - skin injuries: bites, bruises/burns in shape of an object, glove/stocking distribution of burns, bruises of various ages, bruises in protected areas
  - bone injuries: rib fractures without major trauma, femur fractures age <1 yr, spiral fractures of long bones in non-ambulatory children, metaphyseal fractures in infants, multiple fractures of various ages, complex/multiple skull fractures
  - GU/GI injuries: chronic abdominal/perineal pain, injury to genitals/rectum, STI/pregnancy, recurrent vomiting or diarrhea

Dyslipidemias

Definition
- metabolic disorders characterized by elevations of fasting plasma LDL-cholesterol, and/or triglycerides (TG), and/or low HDL-cholesterol

Overview of Lipid Transport
- lipoproteins are spherical complexes that consist of a lipid core surrounded by a shell of water-soluble cholesterol, apolipoproteins, and phospholipids
- lipoproteins transport lipids within the body
- apolipoproteins serve as enzyme co-factors, promote clearance of the particle by interacting with cellular receptors, and stabilize the lipoprotein micelle
**Table 1. Lipoproteins**

<table>
<thead>
<tr>

</tr>
<tr>
<td>Hepatic: cholestatic liver disease (e.g. primary biliary cirrhosis)</td>
</tr>
<tr>
<td>Nutritional: anorexia nervosa</td>
</tr>
<tr>
<td>Drugs: cyclosporin, carbamazepine</td>
</tr>
</tbody>
</table>

### Dyslipidemia and the Risk for Coronary Artery Disease

- increased LDL is a major risk factor for atherosclerosis and CAD as LDL is the major atherogenic lipid particle
- increased HDL is associated with decreased cardiovascular disease and mortality
- moderate hypertriglyceridemia (triglyceride level 2.3-9 mmol/L) is an independent risk factor for CAD, especially in people with DM and in post-menopausal women
- treatment of hypertriglyceridemia has not been shown to reduce CAD risk

**Screening**
- screen men and women >40 yr or post-menopausal
- if following risk factors present, screen at any age:
  - DM
  - current cigarette smoking or COPD
  - HTN (sBP >140, dBP >90), hypertensive diseases of pregnancy
  - obesity (BMI 30 kg/m²)
  - family history of premature CVD
  - clinical signs of hyperlipidemia (xanthelasma, xanthoma, arcus cornealis)
  - clinical evidence of abdominal atheroma
  - clinical evidence of atherosclerosis
  - inflammatory disease (rheumatoid arthritis, SLE, psoriatic arthritis, ankylosing spondylitis, inflammatory bowel disease)
  - HIV infection on highly active anti-retroviral therapy (HAART)
  - chronic kidney disease (estimated GFR <60 mL/min/1.73 m²)
  - erectile dysfunction
  - high risk ethnicity: south Asian, First Nations
  - screen children with a family history of hypercholesterolemia or chylomicronemia
  - apolipoprotein B (apo B)
  - each atherogenic particle (VLDL, IDL, LDL, and lipoprotein A) contains one molecule of apo B
  - serum [apo B] reflects the total number of particles and may be useful in assessing cardiovascular risk and adequacy of treatment in high risk patients and those with metabolic syndrome
  - Lipoprotein A, (Lp(a)), levels may help stratifying those at intermediate risk
  - coronary artery calcium (CAC) may help stratifying those at intermediate risk
  - C-reactive protein (hs-CRP) levels
    - highly sensitive acute phase reactant
    - may be clinically useful in identifying those at a higher risk of cardiovascular disease than predicted by the global risk assessment

**CVD Risk Assessment**
- Framingham Risk Score (FRS): 10 yr risk of major CVD event. Calculated based on gender, age, total cholesterol, HDL, sBP, and smoking (>20%: high risk; 10-19%: moderate risk; <10% low risk)
- Reynolds Risk Score: 10 yr risk of major CVD event. Calculated based on age, SBP, total cholesterol, HDL, high sensitivity CRP, family history of MI
Treatment of Dyslipidemias

**Risk Assessment & Treatment Consideration**

- **Low Risk**
  - FRS <10%

- **Intermediate Risk**
  - FRS 10-19%
  - LDL-C >3.5 mmol/L
  - or Non-HDL-C >4.3 mmol/L
  - or ApoB >1.2 g/L

- **High Risk**
  - FRS ≥20%

- **Statin-Indicated Conditions**
  - Abdominal aortic aneurysm
  - Chronic kidney disease
  - Most diabetes

**Approach to Treatment**

- Consider treatment for patients with statin-indicated conditions (e.g. Type II DM); risk assessment is not required.
- Risk stratification and treatment: The primary target of therapy is to achieve an LDL <2.0 mmol/L or a 50% reduction in LDL from baseline.

**Table 4. Treatment of Dyslipidemia**

Disorders of Glucose Metabolism

Overview of Glucose Regulation

Pre-Diabetes (Impaired Glucose Tolerance/Impaired Fasting Glucose)

- 1-5% per yr go on to develop DM
- 50-80% revert to normal glucose tolerance
- weight loss may improve glucose tolerance (5-10% of body weight)
- increased risk of developing macrovascular complications (IGT >IFG)
- lifestyle modifications decrease progression to DM by 58%

Diagnostic Criteria (CDA Guidelines)

- impaired fasting glucose (IFG): fasting plasma glucose (FPG) 6.1-6.9 mmol/L
- impaired glucose tolerance (IGT): 2h 75 g oral glucose tolerance test (OGTT) 7.8-11.0 mmol/L
- HbA1c: 6.0-6.4%

Diabetes Mellitus

Definition

- diabetes mellitus is a heterogeneous metabolic disorder characterized by the presence of hyperglycemia due to impairment of insulin secretion, defective insulin action, or both
- chronic hyperglycemia of diabetes is associated with relatively specific long-term microvascular complications affecting the eyes, kidneys and nerves, as well as an increased risk for macrovascular complications such as cardiovascular, stroke, and peripheral vascular disease

Figure 4. Blood glucose regulation

Three Year Efficacy of Complex Insulin Regimens in T2DM: 4T Trial

NEJM 2009;361:1736-1747

Study: Randomized unblinded trial with 3 yr of follow-up.

Population: 708 patients with T2DM, not on insulin or thiazolidinedione therapy on maximal metformin and sulfonylurea therapy.

Intervention: Thrice-daily prandial insulin aspart, versus twice-daily biphasic insulin aspart, versus once-daily basal insulin detemir. Sulfonylurea therapy was replaced with a secondary insulin regime specific to each arm if there was persistent hyperglycemia.

Primary Outcome: Three yr hemoglobin HbA1c.

Results: Significant difference in rates of patient withdrawal from the study: 5.1% biphasic, 11.7% prandial, 0.5% basal regimens (p=0.0001). There were no significant differences in median HbA1c levels between all three arms from yr 1-3. A smaller proportion of patients reached HbA1c <6.5% or <7.0% in the biphasic arm. The basal arm had least weight gain and least weight circumference increase, but highest rate of secondary insulin requirement. The basal arm had fewest severe hypoglycemic events per patient year, while the biphasic had the most serious adverse effects.

Conclusion: Basal insulin regime provides the best glycemic control over a 3 yr study, with better HbA1c control, fewer hypoglycemic events, and less weight gain.

Rosuvastatin to Prevent Vascular Events in Men and Women with Elevated C-Reactive Protein (Jupiter Study)

NEJM 2008;359(21):2195-207

Study: Randomized Control Trial

Intervention: Statin Therapy

Results: Rosuvastatin reduced LDL cholesterol levels by 50% and high-sensitivity C-reactive protein levels by 37%. The rates of the primary end point were 0.77 and 1.36 per 100 person-years of follow-up in the rosvastatin, 0.58, 95% confidence interval (CI), 0.46-0.89, P=0.0001, with corresponding rates of 0.17 and 0.39 for myocardial infarction (hazard ratio, 0.46; 95% CI, 0.30-0.73; P=0.0002), 0.18 and 0.34 for stroke (hazard ratio, 0.52; 95% CI, 0.34-0.79; P=0.0021), 0.41 and 0.77 for revascularization or unstable angina (hazard ratio, 0.52; 95% CI, 0.40-0.70; P=0.0001), 0.45 and 0.85 for the combined end point of myocardial infarction, stroke, or death from cardiovascular causes (hazard ratio, 0.52; 95% CI, 0.40-0.69; P<0.0001), and 1.00 and 1.25 for death from any cause (hazard ratio, 0.80; 95% CI, 0.67-0.97; P=0.02)

Conclusion: Statins reduce the incidence of major cardiovascular events even in healthy people without hyperlipidemia but with elevated C-reactive protein.
Diagnostic Criteria (as per Diabetes Canada 2018 Clinical Practice Guidelines)

- any one of the following is diagnostic:

Table 5. Diagnosis of Diabetes

<table>
<thead>
<tr>
<th>Fasting = no caloric intake for at least 8 hours</th>
<th>or</th>
</tr>
</thead>
<tbody>
<tr>
<td>HbA1C ≥ 6.5% (in adults)</td>

</tr>
<tr>
<td>Random PG ≥ 11.1 mmol/L</td>
<td></td>
</tr>
</tbody>
</table>

- in the presence of hyperglycemia symptoms (polyuria, polydipsia, polyphagia, weight loss, blurry vision), a confirmatory test is not required
- in the absence of hyperglycemic symptoms, a repeat confirmatory test (HbA1C, 2hPG in a 75 g OGTT) done on another day is required for diagnosis of diabetes

Etiology and Pathophysiology

Table 6. Etiologic Classification of Diabetes Mellitus

I. T1DM (immune-mediated β cell destruction, usually leading to absolute insulin deficiency)

II. T2DM (Type 2 diabetes occurs when the pancreas does not produce enough insulin or when the body does not effectively use the insulin that is produced)

III. Other Specific Causes of DM

a. Genetic defects of β cell function (e.g. MODY – Maturity-Onset Diabetes of the Young (also known as monogenic diabetes) or insulin action

b. Diseases of the exocrine pancreas:
   - Pancreatitis, pancreatocyst, neoplasia, cystic fibrosis, hemochromatosis ("bronze diabetes")

c. Endocrinopathies:
   - Acromegaly, Cushing's syndrome, glucagonoma, pheochromocytoma, hyperthyroidism

d. Drug-induced:
   - Glucocorticoids, thyroid hormone, β-adrenergic agonists, thiazides, phenytoin, antipsychotics

e. Infections:
   - Congenital rubella, CMV, coxsackie

f. Genetic syndromes associated with DM:
   - Down’s syndrome, Klinefelter’s syndrome, Turner’s syndrome

IV. Gestational Diabetes Mellitus (see Obstetrics, OB26)

Blood Glucose Control in T2DM – UKPDS 33

Study: RCT (mean follow-up 10 yr).

Patients: 3987 patients with newly diagnosed T2DM (mean age 63 yr, 61% men, 81% white, mean fasting plasma glucose [FPG] 6.1-15.0 mmol/L). Exclusions included severe cardiovascular disease, renal disease, retinopathy, and others.

Intervention: Intensive treatment with sulfonylurea or insulin (target FPG <6 mmol/L) vs. conventional treatment with diet alone (target FPG <15 mmol/L) without hyperglycemic symptoms.

Main Outcomes: DM-related endpoints (MI, angina, heart failure, stroke, renal failure, amputation, retinopathy, blindness, death from hyperglycemia or hypoglycemia), DM-related death, and all-cause mortality.

Results: Patients allocated to intensive treatment had lower median HbA1c levels (p=0.001).

<table>
<thead>
<tr>
<th>Outcome</th>
<th>RR HR (%) (p value)</th>
</tr>
</thead>
<tbody>
<tr>
<td>DM-related endpoint</td>
<td>12 (0.029)</td>
</tr>
<tr>
<td>DM-related death</td>
<td>10 (0.34)</td>
</tr>
<tr>
<td>All-cause mortality</td>
<td>6 (0.44)</td>
</tr>
</tbody>
</table>

Patients allocated to intensive therapy had more hypoglycemic episodes and greater weight gain.

Conclusion: Intensive blood glucose control reduces microvascular, but not macrovascular complications in T2DM.
there may be harm associated with strategy to target HbA1c <6.0% (see sidebar ACCORD Trial, E9)

Table 7. Comparison of Type 1 and Type 2 Diabetes Mellitus (continued)

<table>
<thead>
<tr>
<th>Pathophysiology</th>
<th>Type 1</th>
<th>Type 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Synergistic effects of genetic, immune, and environmental factors that cause β cell destruction resulting in impaired insulin secretion</td>
<td></td>
<td>Impaired insulin secretion, peripheral insulin resistance (likely due to receptor and post-receptor abnormality), and excess hepatic glucose production</td>
</tr>
<tr>
<td>Autoimmune process is believed to be triggered by environmental factors (e.g. viruses, bovine milk protein, urea compounds) Pancreatic cells are infiltrated with lymphocytes resulting in islet cell destruction 80% of β cell mass is destroyed before features of DM present</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Natural History

After initial presentation, honeymoon period often occurs where glycemic control can be achieved with little or no insulin treatment as residual cells are still able to produce insulin Once these cells are destroyed, there is complete insulin deficiency

Earlier on, glucose tolerance remains normal despite insulin resistance as β cells compensate with increased insulin production As insulin resistance and compensatory hyperinsulinemia continue, the β cells are unable to maintain the hyperinsulinemic state which results in glucose intolerance and DM

Circulating Autoantibodies

Islet cell Ab present in up to 60-85%
Most common islet cell Ab is against glutamic acid decarboxylase (GAD)
Up to 60% have Ab against insulin

Risk Factors

Personal history of other autoimmune diseases including Graves’ disease, myasthenia gravis, autoimmune thyroid disease, celiac disease, and pernicious anemia
Family history of autoimmune diseases

Age >40 yr
Schizophrenia
Abdominal obesity/overweight
Fatty liver
First-degree relative with DM
Hyperuricemia
Race/ethnicity (Black, Aboriginal, Hispanic, Asian-American, Pacific Islander)
Hx of IGT or IFG
HTN
Dyslipidemia
Medications e.g. 2nd generation antipsychotics
PCOS
Hx of gestational DM or macrosomic baby (>9 lb or >4 kg)

Body Habitus

Normal to thin
Typically overweight with increased central obesity

Treatment

Insulin
Lifestyle modification
Non-insulin antihyperglycemic agents - unless contraindicated, metformin should be the initial antihyperglycemic agent of choice. Additional agents to be selected on the basis of clinically relevant issues, such as glucose-lowering effectiveness, risk of hypoglycemia, and effect on body weight
Insulin therapy

Acute Complication

Diabetic ketoacidosis (DKA) in severe cases
Hyperosmolar hyperglycemic state (HHS) DKA in severe cases

Screening

Subclinical prodrome can be detected in first and second-degree relatives of those with T1DM by the presence of pancreatic islet autoantibodies
Screen individuals with risk factors

**Treatment of Diabetes**

**Glycemic Targets**
- HbA1c reflects glycemic control over 3 mo and is a measure of patient’s long-term glycemic control
- therapy in most individuals with T1DM or T2DM (especially younger patients) should be targeted to achieve a HbA1c ≤7.0% in order to reduce the risk of microvascular and if implemented early in the course of disease, macrovascular complications
- more intensive glucose control, HbA1c <6.5%, may be targeted in patients with a shorter duration of DM with no evidence of significant CVD and longer life expectancy, to further reduce risk of nephropathy and retinopathy, provided this does not result in a significant increase in hypoglycemia
- less stringent HbA1c targets (7.1-8.5%) may be more appropriate in patients with limited life expectancy, higher level of functional dependency, a history of recurrent severe hypoglycemia, multiple comorbidities, extensive CAD, or a failure to achieve an HbA1c <7.0% despite intensified basal and bolus insulin therapy
- there may be harm associated with strategy to target HbA1c <6.0% (see sidebar ACCORD Trial, E9)
**Disorders of Glucose Metabolism**

**Diet**
- daily carbohydrate intake 45-60% of energy, protein 15-20% of energy, and fat <35% of energy
- intake of saturated fats <7% and polyunsaturated fats <10% of total calories each
- limit sodium, alcohol, and caffeine intake
- Type 1: carbohydrate counting is used to titrate prandial insulin dose
- Type 2: weight reduction to help control blood glucose levels

**Lifestyle**
- regular physical exercise to improve insulin sensitivity, lower lipid concentrations, and control blood pressure. At least 150 minutes per week of aerobic exercise and at least 2 sessions per week of resistance exercise are recommended
- smoking cessation

**Medical Treatment: Non-Insulin Antihyperglycemic Agents (T2DM)**
- initiate non-insulin antihyperglycemic therapy within 2-3 mo if lifestyle management does not result in glycemic control
- if initial HbA1c >8.5% at the time of diagnosis, initiate pharmacologic therapy with metformin immediately, and consider combination of therapies or insulin immediately
- continue to add additional pharmacologic therapy in a timely fashion to achieve target HbA1C within 3-6 mo of diagnosis
- see Common Medications, E52 for details on antihyperglycemic agents

**Medical Treatment: Insulin**
- used for T1DM at onset, may be used in T2DM at any point in treatment
- routes of administration: subcutaneous injections, continuous subcutaneous insulin infusion pump, IV infusion (regular insulin only)
- basal insulin: control blood sugar (produced by liver) during periods of fasting; slow onset of action, lasts a long time
- bolus insulin: required to dispose of glucose from a meal; rapid onset of action, short acting
- bolus insulins: short-acting (Insulin regular), rapid-acting analogue (Insulin aspart, Insulin glulisine, Insulin lispro)
- basal insulins: intermediate-acting (Insulin NPH), long-acting analogue (Insulin detemir, glargine, degludec)
- premixed insulins (combination of basal and bolus insulins), 30/70 insulin mixture, Humalog® mix 25, Novorapid® mix 30
- estimated total daily insulin requirement: often start with 0.3-0.5 units/kg/d

**Effects of Intensive Glucose Lowering in T2DM:**
- **The ACCORD Trial**
  - NEJM 2008;359:212-229
  - Study: Multicentre RCT.
  - Patients: 7933 patients with T2DM, risk factors for cardiovascular (CV) disease, HbA1c level <7% or standard therapy targeting a HbA1c level of <6.0% or standard therapy targeting 7.6-7.9%.
  - Outcomes: First occurrence of nonfatal MI, nonfatal stroke, or death from CV causes.
  - Results: Intensive therapy arm was stopped early (3.5 yr vs. 6.5 yr planned) due to evidence of increased mortality. There was no difference in primary outcome for either study arm. There was a significant increase in all-cause mortality, CV mortality, nonfatal MI, and CHF in the intensive therapy group. There were increased rates of all hypoglycemic events, any nonhypoglycemic serious adverse events, fluid retention, and weight gain >10 kg, but lower systolic and diastolic blood pressure in the intensive therapy group. There was an increased incidence of elevated ALT (3x upper limit) and ACE drug use in the standard therapy group.
  - Conclusions: Intensive glucose lowering therapy in T2DM does not improve clinic outcomes and actually increases the risk of mortality with more adverse events compared to standard therapy. Additional research is required to discern the cause.

**Effects of Intensive Blood Pressure Control in T2DM:**
- **The ACCORD Trial**
  - NEJM 2008;358:2545-2559
  - Study: RCT, unblinded with 4.7 yr of mean follow-up.
  - Population: 4733 patients with T2DM, risk factors for cardiovascular (CV) disease, systolic blood pressure (SBP) between 130-180 mmHg.
  - Intervention: SBP control less than 120 mmHg (intensive) or 140 mmHg (standard).
  - Primary Outcomes: Major CV event (composite nonfatal MI, nonfatal stroke, or CV-related death).
  - Results: Mean number of medications at 1 yr for intensive therapy was 2.4 (95% CI 2.4-2.5) versus 2.1 (95% CI 2.1-2.2) for standard therapy. There was a significant increase in all serious adverse events in the intensive treatment arm (3.3% vs. 1.2%, p=0.001), especially bradycardia or atrial fibrillation (0.5% vs. 0.3%, p=0.01), hyperkalemia (0.4% vs. 0.1%, p=0.01). There was no significant difference in primary outcomes in the two study arms, or all-cause mortality. There was a significant reduction in all stroke (0.32% vs. 0.53%, p=0.01) and nonfatal stroke incidences (0.30% vs. 0.47%, p=0.03) in the intensive therapy arm.
  - Conclusions: Intensive BP lowering to less than 120 mmHg vs. 140 mmHg in patients with T2DM and CV risk factors does not reduce major CV event risk reduction except for stroke events.

<tr>
<td>Start at a low dose of 5-10 U BID (before breakfast and before dinner)</td>
<td></td>
</tr>
<tr>
<td>Patients can self-titrate by increasing insulin dose by 1 U/d until pre-dinner (breakfast dose) or fasting BG (dinner dose) at target</td>
<td></td>
</tr>
<tr>
<td>Continue metformin and consider stopping secretagogue</td>
<td></td>
</tr>
</tbody>
</table>

- Correction Factor (CF) = 100/Total Daily Dose of insulin (TDD) = change in blood glucose per unit insulin
  - BG <4: call MD and give 15 g carbohydrates
  - BG between 4 to 8: no additional insulin
  - BG between 8 to (8 + CF): give one additional unit
  - BG between (8 + CF) to (8 + 2CF): give two additional units
  - BG between (8 + 2CF) to (8 + 3CF): give three additional units

**Insulin Pump Therapy: Continuous Subcutaneous Insulin Infusion (CSII)**

- external battery-operated device provides continuous basal dose of rapid-acting insulin analogue (aspart, glulisine, or lispro) through small subcutaneous catheter
- at meals, patient programs pump to deliver insulin bolus
- provides improved quality of life and flexibility
- risk of DKA if pump is inadvertently disconnected
- coverage available for insulin pumps for individuals with T1DM varies by province
Table 12. Acute Complications of Diabetes Mellitus: Hyperglycemic Comatose States

<table>
<thead>
<tr>
<th>Diabetic Ketoacidosis (DKA)</th>
<th>Hyperosmolar Hyperglycemic State (HHS)</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Pathophysiology</strong></td>
<td><strong>Onset is insidious → preceded by weakness, polyuria, polydipsia</strong></td>
</tr>
<tr>
<td>• Usually occurs in T1DM</td>
<td>• Occurs in T2DM</td>
</tr>
<tr>
<td>• Insulin deficiency with ↑ counterregulatory hormones (glucagon, cortisol, catecholamines, GH)</td>
<td>• Often precipitated by sepsis, stroke, MI, CHE, renal failure, trauma, drugs (glucocorticoids, immunosuppressants, phenytoin, diuretics, dialysis, recent surgery, burns)</td>
</tr>
<tr>
<td>• Can occur with lack of insulin (non-adherence, inadequate dosage, 1st presentation) or increased stress (surgery, infection, exercise)</td>
<td>• Partial or relative insulin deficiency decreases glucose utilization in muscle, fat, and liver while inducing hyperglycunagomia and hepatic glucose production</td>
</tr>
<tr>
<td>• Unopposed hepatic glucose production → hyperglycemia → osmotic diuresis → dehydration and electrolyte disturbance → ↓ Na+ (water shift to ECF causing pseudohyponatremia)</td>
<td>• Presence of a small amount of insulin prevents the development of ketosis by inhibiting lipolysis</td>
</tr>
<tr>
<td>• Fat mobilization → ↑ FFA → ketoads → metabolic acidosis</td>
<td>• Characterized by hyperglycemia, hyperosmolality, and dehydration without ketosis</td>
</tr>
<tr>
<td>• Severe hyperglycemia exceeds the renal threshold for glucose and ketone reabsorption → glucosuria and ketonuria</td>
<td>• More severe dehydration compared to DKA due to more gradual onset and ↓ duration of metabolic decompensation plus impaired fluid intake which is common in bedridden or elderly</td>
</tr>
<tr>
<td>• Total body K+ depletion but serum K+ may be normal or elevated. 2º to shift from ICF to ECF due to lack of insulin, ↑ plasma osmolality</td>
<td>• Volume contraction → renal insufficiency → ↑ hyperglycemia, ↑ osmolality → shift of fluid from neurons to ECF → mental obtundation and coma</td>
</tr>
<tr>
<td></td>
<td><strong>Clinical Features</strong></td>
</tr>
<tr>
<td></td>
<td>• Hyperglycemia (polyuria, polydipsia, weakness)</td>
</tr>
<tr>
<td></td>
<td>• Acidosis (air hunger, nausea, vomiting, abdominal pain, Kussmaul’s respiration, acetone-odoured breath)</td>
</tr>
<tr>
<td></td>
<td>• Precipitating conditions (insulin omission, new diagnosis of diabetes, infection, MI, thyrotoxicosis, drugs)</td>
</tr>
<tr>
<td></td>
<td>• Onset is insidious → preceded by weakness, polyuria, polydipsia</td>
</tr>
<tr>
<td></td>
<td>• History of decreased fluid intake</td>
</tr>
<tr>
<td></td>
<td>• History of ingesting large amounts of glucose containing fluids</td>
</tr>
<tr>
<td></td>
<td>• Dehydration (orthostatic changes)</td>
</tr>
<tr>
<td></td>
<td>• ↓ LOC → lethargy, confusion, comatose due to high serum osmolality</td>
</tr>
<tr>
<td></td>
<td>• Kussmaul’s respiration is absent unless the underlying precipitant has also caused a metabolic acidosis</td>
</tr>
<tr>
<td><strong>Serum</strong></td>
<td>• ↑ BG (typically 11-55 mmol/L, ↓ Na+ 12º to hyperglycemia → for every ↑ in BG by 10 mmol/L there is a ↓ in Na+ by 3 mmol/L)</td>
</tr>
<tr>
<td></td>
<td>• Normal or ↑ K+, ↓ HCO3−, ↑ BUN, ↑ Cr, ketonemia, ↓ PO2</td>
</tr>
<tr>
<td></td>
<td>• ↑ osmolality</td>
</tr>
<tr>
<td></td>
<td>• corrected sodium = current sodium + [0.3 x (current glucose -5)]</td>
</tr>
<tr>
<td></td>
<td>• ↑ BG (typically 44.4-133.2 mmol/L)</td>
</tr>
<tr>
<td></td>
<td>• In mild dehydration, may have hyponatremia (spurious 2º to hyperglycemia → for every ↑ in BG by 10 mmol/L there is a ↓ in Na+ by 3 mmol/L)</td>
</tr>
<tr>
<td></td>
<td>• ↓ if dehydration progresses, may get hypernatremia</td>
</tr>
<tr>
<td></td>
<td>• Ketosis usually absent or mild if starvation occurs</td>
</tr>
<tr>
<td></td>
<td>• ↑ osmolality</td>
</tr>
<tr>
<td><strong>ABG</strong></td>
<td>• Anion Gap metabolic acidosis with possible 2º respiratory alkalosis</td>
</tr>
<tr>
<td></td>
<td>• If severe vomiting/dehydration there may also be a metabolic alkalosis</td>

<tr>
<td></td>
<td>• Metabolic acidosis absent unless underlying precipitant leads to acidosis (e.g. lactic acidosis in MI)</td>
</tr>
<tr>
<td><strong>Urine</strong></td>
<td>• +ve for glucose and ketones</td>
</tr>
<tr>
<td></td>
<td>• -ve for ketones unless there is starvation ketosis</td>
</tr>
<tr>
<td></td>
<td>• Glycosuria</td>
</tr>
<tr>
<td><strong>Treatment</strong></td>
<td>• ABCs are first priority</td>
</tr>
<tr>
<td></td>
<td>• Monitor degree of ketoacidosis with AC, not BG or serum ketone level</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE:</strong> Anion gap is the most important endpoint used to monitor the resolution of the metabolic acidosis</td>
</tr>
<tr>
<td></td>
<td>• Rehydration</td>
</tr>
<tr>
<td></td>
<td>• 500 mL/h x 4 h, then 250 mL/h x 4 h NS x 4 if mild-moderate deficit, 1-2 L/h NS if severe deficit (shock)</td>
</tr>
<tr>
<td></td>
<td>• Switch to 0.45% NaCl once euvoletic (continue NS if corrected [Na+] is low or rate of fall of plasma osmolality ≥3 mosm/kg/h)</td>
</tr>
<tr>
<td></td>
<td>• once BG reaches 14.0 mmol/L add D5W or D10W to maintain BG of 12-14 mmol/L</td>
</tr>
<tr>
<td></td>
<td>• Insulin therapy</td>
</tr>
<tr>
<td></td>
<td>• critical to resolve acidosis, not hyperglycemia</td>
</tr>
<tr>
<td></td>
<td>• do not use with hypokalemia (see below), until serum K+ is corrected to ≥3.3 mmol/L</td>
</tr>
<tr>
<td></td>
<td>• use only regular insulin (R)</td>
</tr>
<tr>
<td></td>
<td>• maintain on 0.1 U/kg/h insulin R infusion</td>
</tr>
<tr>
<td></td>
<td>• check serum glucose hourly</td>
</tr>
<tr>
<td></td>
<td>• K+ replacement</td>
</tr>
<tr>
<td></td>
<td>• with insulin administration, hypokalemia may develop</td>
</tr>
<tr>
<td></td>
<td>• if serum K+&lt;3.3 mmol/L, give 40 mEq/L K+ replacement and hold insulin until K+[1] ≥3.3 mmol/L</td>
</tr>
<tr>
<td></td>
<td>• when K+[1] 3.3-5.5 mmol/L add KCl 10-40 mEq/L to keep K+[1] in the range of 3.5-5.5 mEq/L</td>
</tr>
<tr>
<td></td>
<td>• HCO3−</td>
</tr>
<tr>
<td></td>
<td>• if pH&lt;7.0 or if hypotension, arrhythmia, or coma is present give HCO3− 1 ampoule (80 mmol) in 200 mL D5W or sterile water if available) over 1 h, repeated q1-2h until pH ≥7.3</td>
</tr>
<tr>
<td></td>
<td>• do not give if pH &gt;7.1 (risk of metabolic alkalosis)</td>
</tr>
<tr>
<td></td>
<td>• can give in case of life-threatening hyperkalemia</td>
</tr>
<tr>
<td><strong>Prognosis</strong></td>
<td>• &lt;1-3.3% mortality in developed countries</td>
</tr>
<tr>
<td></td>
<td>• Serious morbidity from sepsis, hypokalemia, respiratory complications, thromboembolic complications, and cerebral edema (the latter in children)</td>
</tr>
<tr>
<td></td>
<td>• Mortality rates between 12-17%, but studies looking at this included mixed DKA/HHS state</td>
</tr>
</tbody>
</table>
Macrovascular Complications

- increased risk of CAD, ischemic stroke, and peripheral arterial disease secondary to accelerated atherosclerosis
- CAD (see Cardiology and Cardiac Surgery, C25)
  - risk of MI is 3-5x higher in those with DM compared to age-matched controls
  - CAD is the leading cause of death in T2DM
- most patients with DM are considered “high risk” under the risk stratification for CAD (see Dyslipidemias, E2)
- ischemic stroke (see Neurology, N50)
  - risk of stroke in those with DM is approximately 2-3x higher for men and 2-5x higher for women
  - level of glycemia is both a risk factor for stroke and a predictor of a poorer outcome in patients who suffer a stroke
  - HbA1c level is a significant and independent predictor of the risk of stroke
- peripheral arterial disease (see Vascular Surgery, V52)
  - manifested by intermittent claudication in lower extremities, absent aortic, foot ulceration
- risk of foot gangrene is 30x higher in those with DM compared to age-matched controls
- risk of lower extremity amputation is 15x higher in those with DM
- treatment
  - tight blood pressure control (<130/80 mmHg); especially for stroke prevention
  - tight glycemic control in early DM without established CVD (refer to ACCORD, VADT, ADVANCE, DCCT, EDIC, UKPDS extension studies)
  - tight low density lipoprotein (LDL) cholesterol control (LDL ≤2.0 mmol/L)
  - ACEI or angiotensin receptor blocker in high-risk patients
  - smoking cessation
  - for adults with CVD who do not meet glycemic targets, recommended to add anti-hyperglycemic agent with demonstrated cardiovascular benefit (empagliflozin or liraglutide) to reduce the risk of major cardiovascular events

Microvascular Complications

DIABETIC RETINOPATHY (see Ophthalmology, OP33 for a more detailed description)

Epidemiology
- diabetic retinopathy is the most common cause of incident blindness in people of working age
- among individuals with T1DM, limb amputation and vision loss due to diabetic retinopathy are independent predictors of early death

Clinical Features
- macular edema: diffuse or focal vascular leakage at the macula
- non-proliferative (microaneurysms, intraretinal hemorrhage, vascular tortuosity, vascular malformation) and proliferative (abnormal vessel growth)
- retinal capillary closure

Treatment and Prevention
- tight glycemic control (delays onset, decreases progression), tight lipid control, manage HTN, smoking cessation
- ophthalmological treatments available (see Ophthalmology, OP33 for more details)
- annual follow-up visits with an optometrist or ophthalmologist examination through dilated pupils whether symptomatic or not (immediate referral after diagnosis of T2DM; 5 yr after diagnosis of T1DM for those ≥15 yr)
- interval for follow-up should be tailored to severity of retinopathy

DIABETIC NEPHROPATHY (see Nephrology, NP31 for a more detailed description)

Epidemiology
- DM-induced renal failure is the most common cause of renal failure in North America
- 20-40% of persons with T1DM (after 5-10 yr) and 4-20% with T2DM have progressive nephropathy

Screening
- serum creatinine for eGFR, random urine albumin to creatine ratio (ACR)
- ACR is used as albuminuria is considered the earliest clinical sign of diabetic nephropathy (microalbuminuria); diagnosis requires persistent elevated urinary albumin (2 out of 3 urinary samples required over 3 mo)
- 24 h urine collection for protein/albumin is the gold standard but is difficult to perform, inconvenient, and often incorrect; random urine albumin is insufficient as albumin levels vary with urine concentration
- begin screening annually at diagnosis for all T2DM, and >5 yr after diagnosis of T1DM for postpubertal patients

Laboratory Testing: Ketones
- The nitroprusside test for ketones identifies acetone and acetoacetate but does NOT detect β-hydroxybutyrate (BHB), the ketone most frequently in excess. This has two clinical consequences:
  - Be wary of a patient with a clinical picture of DKA but negative serum or urinary ketones. These could be false negatives because of the presence of BHB
  - As DKA is treated, BHB is converted to acetone and acetoacetate. Serum or urinary ketones may therefore rise, falsely suggesting that the patient is worsening when in fact they are improving

Empagliflozin, Cardiovascular Outcomes, and Mortality in T2DM
NEJM 2015;373:2117-2128
- Purpose: To examine whether empagliflozin (an SGLT2 inhibitor) has any effect on cardiovascular risk in patients with T2DM.
- Study: Multi-centre RCT comparing empagliflozin to placebo control; 7020 patients (test N=4687, placebo N=2333), median observation 3.1 yr.
- Outcome: Death from cardiovascular causes, nonfatal MI, or nonfatal stroke.
- Results: Both groups concurrently received the standard treatment for T2 DM. The empagliflozin group had significantly lower rates of death from cardiovascular causes than control (0.7%, vs. 1.1%, 39% decreased relative risk). The test group also had lower all-cause mortality (5.7% and 8.3%, respectively; 32% decreased relative risk).
- Conclusion: Adding empagliflozin to standard treatment for T2DM reduced death from macrovascular complications and all-cause mortality when compared to placebo.

Liraglutide and Cardiovascular Outcomes in T2DM
NEJM 2016; 375:311-322
- Purpose: To investigate whether liraglutide (a GLP-1 analogue) has any effect on cardiovascular risk in patients with T2DM when added to standard care.
- Study: Multi-centre, double-blind RCT comparing liraglutide to placebo control; 9340 patients (test N=4668, placebo N=4672), median observation 3.1 yr.
- Outcome: Death from cardiovascular causes, nonfatal MI, or nonfatal stroke.
- Results: Both groups concurrently received the standard treatment for T2 DM. The liraglutide group had any effect on cardiovascular outcomes when compared to placebo.
Treatment and Prevention
- appropriate glycemic control
- appropriate blood pressure control (<130/80 mmHg)
- use either ACEI or ARB to delay progression of CKD (often used first line for their CVD protection)
- limit use of nephrotoxic drugs and dyes

DIABETIC NEUROPATHY

Epidemiology
- approximately 50% of patients within 10 yr of onset of T1DM and T2DM

Pathophysiology
- can have peripheral sensory neuropathy, motor neuropathy, or autonomic neuropathy
- mechanism poorly understood
- acute cranial nerve palsies and diabetic amyotrophy are thought to be due to ischemic infarction of peripheral nerve
- the more common motor and sensory neuropathies are thought to be related to metabolic, vascular, and perhaps hormonal factors

Screening
- 128 Hz tuning fork or 10 g monofilament
- begin screening annually at diagnosis for all T2DM, and >5 yr after diagnosis of T1DM for post-pubertal patients

Clinical Features

Table 13. Clinical Feature of Diabetic Neuropathies

| Paresthesia (tingling, itching) | Less common than sensory neuropathy and occur later in the disease process |
| neuropathic pain, radicular pain, numbness, decreased tactile sensation | Delayed motor nerve conduction and muscle weakness/atrophy |
| Bilateral and symmetric with decreased perception of vibration and pain/temperature; especially true in the lower extremities but may also be present in the hands | May involve one nerve trunk (mononeuropathy) or more (mononeuritis multiplex) |
| Decreased ankle reflex | Some of the motor neuropathies spontaneously resolve after 6-8 wk |
| Distal–predominant – longest nerves affected first | Reversible CN palsies: III (ptosis, ophthalmoplegia, pupil sparing), VI (inability to laterally deviate eye), and VII (Bell’s palsy) |
| Classic stocking–glove distribution | Diabetic amyotrophy i.e. Bruns-Garland Syndrome: refers to pain, weakness, and wasting of hip flexors or extensors |
| May result in neuropathic ulceration of foot | Postural hypotension, tachycardia, decreased cardiovascular response to valsalva maneuver |

Treatment and Management
- tight glycemic control
- for neuropathic pain syndromes: tricyclic antidepressants (e.g. amitriptyline), pregabalin, duloxetine, anti-epileptics (e.g. carbamazepine, gabapentin), and capsacin
- foot care education
- job fit stocking and tilting of head of bed may decrease symptoms of orthostatic hypotension
- treat gastroparesis with domperidone and/or metoclopramide (dopamine antagonists), erythromycin (stimulates motilin receptors)
- medical, mechanical, and surgical treatment for erectile dysfunction (see Urology, U33)

Other Complications

Dermatologic
- diabetic dermopathy: atrophic brown spots commonly in pretibial region known as “tibia spots”, secondary to increased glycosylation of tissue proteins or vasculopathy
- eruptive xanthomas secondary to increased triglycerides
- necrobiosis lipoidica diabeticorum: rare complication characterized by thinning skin over the shins
- eruptive xanthomas secondary to increased triglycerides
- diabetes mellitus: atrophy of skin over joints secondary to glycosylated collagen and other connective tissue proteins
- Dupuytren’s contracture
- increased fracture risk in both T1DM and T2DM due to increased bone demineralization
- adhesive capsulitis (“frozen shoulder”)

Bone and Joint Disease
- juvenile cheiroarthropathy: chronic stiffness of hand caused by contracture of skin over joints secondary to glycosylated collagen and other connective tissue proteins
- Dupuytren’s contracture
- increased fracture risk in both T1DM and T2DM due to increased bone demineralization
- adhesive capsulitis (“frozen shoulder”)
Cataracts
- subcapsular and senile cataracts secondary to glycosylated lens protein or increased sorbitol causing osmotic change and fibrosis

Infections
- see Infectious Diseases, ID13

Hypoglycemia

Etiology and Pathophysiology
- hypoglycemia occurs most frequently in people with DM receiving insulin or certain antihyperglycemic therapies (insulin secretagogues)
- in people without DM, care must be taken to distinguish hypoglycemia that occurs in critically ill or medicated patients from hypoglycemia that presents in individuals who are seemingly well
  - each invokes separate diagnostic pathways
  - the timing of hypoglycemia may also provide a clue to the diagnosis (e.g. individuals with an insulinoma typically have fasting hypoglycemia whereas those with noninsulinoma pancreaticogenous hypoglycemia experience predominantly postprandial hypoglycemia)

Table 14. Causes of Hypoglycemia

</tbody>
</table>

Clinical Features
- Whipple’s triad – suggest a patient’s symptoms are from hypoglycemia
  1. serum glucose <4.0 mmol/L
  2. neuroglycopenic symptoms (below)
  3. rapid relief provided by administration of glucose
- autonomic symptoms (typically occur first; caused by autonomic nervous system activity)
  - palpitations, sweating, anxiety, tremor, tachycardia, hunger
- neuroglycopenic symptoms (caused by brain glucose deprivation)
  - dizziness, headache, clouding of vision, mental dullness, fatigue, confusion, seizures, coma

Investigations
- depend on a thorough history, physical exam, and available biochemical investigations as these may provide clues to the etiology of hypoglycemia
  - for example, if suspecting insulin and insulin secretagogues in patients with diabetes, assess for cortisol deficiency. In a patient with weight loss, hyperpigmentation, and hyperkalemia, consider the possibility of IGF-2 mediated hypoglycemia. In an individual with a gastrointestinal stromal tumour (GIST), think about renal/hepatic failure in the setting of critical illness
- when the cause of hypoglycemia is not evident, screen for oral hypoglycemic agents and measure plasma glucose, serum ketones, insulin, pro-insulin, C-peptide, and insulin antibodies during a spontaneous hypoglycemic episode or a supervised fast of up to 72 h. If hypoglycemia occurs only in the postprandial state, evaluate the patient first with a mixed meal test

Treatment
- for tumoural hypoglycemia, definitive treatment requires resection of the tumour. If that is not possible certain medications can be helpful such as diazoxide for patients with insulinoma
  - for noninsulinoma pancreaticogenous hypoglycemia and post-bariatric bypass hypoglycemia, dietary changes including reducing the amount of carbohydrate intake and small frequent meals may be helpful. For patients who do not respond to nutritional modification or have severe symptoms acarbose can be utilized
- see Emergency Medicine, ER35
  - treatment of hypoglycemic episode in the unconscious patient or patient NPO
    - D50W 50 mL (1 ampule) IV in 1-3 min or 1 mg glucagon SC or IM (if no IV access is available)
    - may need ongoing glucose infusion once BG >5 mmol/L

- Cortisol
- Epinephrine
- Glucagon

Other Players in Glucose Homeostasis
- These hormones act to increase blood glucose levels
  - Glucagon
  - Epinephrine
  - Cortisol
  - Growth hormone

C-Peptide
- A short peptide released into the circulation when proinsulin is cleaved to insulin

Use C-peptide Levels to Distinguish between Exogenous and Endogenous Source of Hyperinsulinemia
- Increased = endogenous
- Decreased or normal = exogenous

Treatment of Acute Hypoglycemic Episode (Blood Glucose <6.0 mmol/L in the Awake Patient)
- 1) Eat 15 g of carbohydrates (CHO) (e.g. 3 packets sugar dissolved in water; 3/4 cup of juice)
- 2) Wait 15 min
- 3) Retest Blood Glucose (BG)
- 4) Repeat steps 1-3 until BG >5 mmol/L
- 5) Eat next scheduled meal. If next meal is >1 h away, eat snack including 15 g of CHO and protein

Hypoglycemia Unawareness (T1DM >>> T2DM)
- Patient remains asymptomatic until severely hypoglycemic levels are reached
- Causes:
  - Decreased glucagon/epinephrine response
  - History of repeated hypoglycemia or low HbA1c
  - Autonomic neuropathy
  - Not safe for patient to drive
- Suggest that patient obtain a Medic-Alert bracelet if at risk for hypoglycemia, especially with hypoglycemia unawareness

5 to Drive
- BG must be >5 mmol/L to drive
**Metabolic Syndrome**

- postulated syndrome related to insulin resistance associated with hyperglycemia, hyperinsulinemia, HTN, central obesity, and dyslipidemia
- obesity aggravates extent of insulin resistance
- complications include DM, atherosclerosis, CAD, MI, and stroke
- women with PCOS are at increased risk for developing insulin resistance, hyperlipidemia, and metabolic syndrome
- not to be confused with syndrome X related to angina pectoris with normal coronary arteries (Prinzmetal angina)

**Obesity**

- see Family Medicine, FM7

**Pituitary Gland**

**Pituitary Hormones**

**Figure 8. Hypothalamic-pituitary hormonal axes**

- CRH = corticotropin-releasing hormone; GHRH = growth hormone-releasing hormone; GnRH = gonadotropin-releasing hormone; PRH = prolactin-releasing hormone; TRH = thyrotropin-releasing hormone

**Hypothalamic Control of Pituitary**

- trophic and inhibitory factors control the release of pituitary hormones
- most hormones are primarily under trophic stimulation except prolactin, which is primarily under inhibitory control by dopamine. GH and TSH are stimulated by GHRH and TRH respectively; less important for control is their inhibition by somatostatin
- transection of the pituitary stalk (i.e. dissociation of hypothalamus and pituitary) leads to pituitary hypersecretion of prolactin and hyposecretion of all remaining hormones

**Anterior Pituitary Hormones**

- follicle stimulating hormone (FSH), luteinizing hormone (LH), adrenocorticotropic hormone (ACTH), thyroid stimulating hormone (TSH), prolactin, growth hormone (GH)

**Posterior Pituitary (Hypothalamic) Hormones**

- antidiuretic hormone (ADH) and oxytocin
- peptides synthesized in the supraoptic and paraventricular nuclei of the hypothalamus
- although ADH and oxytocin are produced in the hypothalamus, these hormones are stored, and released from the posterior pituitary

**Features of Metabolic Syndrome**

### Table 15. The Physiology and Action of Pituitary Hormones

<table>
<thead>
<tr>
<th>Hormone</th>
<th>Function</th>
<th>Physiology</th>
<th>Inhibitory Stimulus</th>
<th>Secretory Stimulus</th>
</tr>
</thead>
</table>
| LH/FSH  | Stimulate gonads via cAMP  
Ovary:  
LH: production of androgens (thecal cells) which are converted to estrogens (granulosa cells); induces luteinization in follicles  
FSH: growth of granulosa cells in ovarian follicle; controls estrogen production  
Testes:  
LH: production of testosterone (Leydig cells)  
FSH: production of spermatogenesis | Polypeptide  
Glycoproteins (similar α subunit as TSH and hCG)  
Secreted in pulsatile fashion | Estrogen  
Progesterone  
Testosterone  
Inhibit  
(i.e. non-pulsatile)  
GnRH infusion | Pulsatile GnRH (low frequency pulsation = FSH release, high frequency pulsation = LH release) |
| ACTH    | Stimulates growth of adrenal cortex and secretion of its hormones | Polypeptide  
Pulsatile and diurnal variation (highest in AM, lowest at midnight) | Dexamethasone, cortisol, and other glucocorticoids | CRH  
Metyrapone  
Insulin-induced hypoglycemia  
Vasopressin  
Fever, pain, stress |
| TSH     | Stimulates growth of thyroid and secretion of T3 and T4 via cAMP | Glycoprotein  
Note: hCG can act like TSH and react with TSH receptor | Thyroid hormones (T3, T4) and analogues, dopamine, somatostatin, cytokines, high dose glucocorticoids | TRH  
AVP  
α adrenergic agonist |
| Prolactin| Promotes milk production  
Inhibits GnRH secretion | Polypeptide  
Episodic secretion | Dopamine (only pituitary hormone under tonic inhibition of secretion) | Sleep  
Stress, hypoglycemia  
Pregnancy, breastfeeding  
Mid-menstrual cycle  
Sexual activity  
TRH  
Drugs: antipsychotics, tricyclic antidepressants, metoclopramide, domperidone, verapamil, methyldopa, opioids, high dose estrogen |
| GH      | Needed for linear growth  
Stimulates secretion of IGF-1, a potent growth and differentiation factor | Polypeptide  
Acts indirectly through IGF-1 (somato-medin-C) synthesized in the liver  
Only anterior pituitary hormone that also acts directly on peripheral target cells  
Serum GH undetectable for most of the day and suppressed after meals high in glucose  
Sustained rise during sleep | Glucose challenge  
Glucocorticoids  
Somatostatin  
Dopamine D2 receptor agonists  
IGF-1 (long-loop) | GHRH  
Insulin-induced hypoglycemia  
Ghrelin  
Exercise  
REM sleep  
Arginine, clonidine, propranolol, L-dopa  
Sex hormones |
| ADH     | Acts at renal collecting ducts on V2 receptors to cause insertion of aquaporin channels and increases water reabsorption thereby concentrating urine | Octapeptide  
Secreted posterior pituitary  
Osmoreceptors in hypothyalamus detect serum osmolality  
Contracted plasma volume detected by baroreceptors is a more potent stimulus than ↑ osmolality | ↓ serum osmolality | Hypovolemia or ↓ effective circulatory volume  
T serum osmolality  
Stress, pain, fever, paraneoplastic  
Lung or brain pathology |
| Oxytocin| Causes uterine contraction  
Breast milk secretion | Nonapeptide  
Secreted posterior pituitary | EtOH | Suckling  
Distention of female genital tract during labour via stretch receptors |
GH EXCESS

Etiology
- GH secreting pituitary adenoma, neuroendocrine tumours secreting ectopic GH or GHRH (very rare)

Pathophysiology
- normally GH is a catabolic hormone that acts to increase blood glucose levels
- in GH excess states, secretion remains pulsatile but there is loss of hypoglycemic stimulation, glucose suppression, and the nocturnal surge
- proliferation of bone, cartilage, soft tissues, organomegaly
- insulin resistance and impaired glucose tolerance (IGT)

Clinical Features
- in children (before epiphyseal fusion) leads to gigantism
- in adults (after epiphyseal fusion) leads to acromegaly
- dermatologic (thickening of skin, increased sebum production, sweating, acne, sebaceous cysts), musculoskeletal (enlargement of hands and feet, coarsening of facial features, thickening of calvarium, prognathism, carpal tunnel syndrome, osteoarthritis), cardiac/metabolic (HTN, DM, acanthosis nigricans, cardiomyopathy), sleep apnea, sexual (low libido)

Investigations
- first line test: serum IGF-1 (expected to be elevated)
- glucose suppression test is the most specific test (75 g of glucose PO suppresses GH levels in healthy individuals but not in patients with acromegaly)
- CT, MRI, or skull x-rays may show cortical thickening, enlargement of the frontal sinuses, and enlargement and erosion of the sella turcica
- MRI of the sella turcica is needed to look for a tumour

Treatment
- surgery, octreotide (somatostatin analogue), dopamine agonist (cabergoline), GH receptor antagonist (pegvisomant), radiation

Prolactin

HYPERPROLACTINEMIA

Etiology
- prolactinoma: most common pituitary adenoma (prolactin-secreting tumours may be induced by estrogens and grow during pregnancy)
- pituitary masses with pituitary stalk compression causing reduced dopamine inhibition of prolactin release
- primary hypothyroidism (increased TRH)
- decreased clearance due to chronic renal failure or severe liver disease (prolactin is metabolized by both the kidney and liver)
- medications with anti-dopaminergic properties are a common source of high prolactin levels: antipsychotics (common), antidepressants, antihypertensives (verapamil/methyldopa), anti-migraine agents (triptans/ergotamines), bowel motility agents (metoclopramide/domperidone), H2-blockers (ranitidine)
- macroprolactinemia (high molecular weight prolactin also known as big-big prolactin) that has no action

Clinical Features
- galactorrhea (secretion of breast milk in women and, in rare cases, men), infertility, hypogonadism, amenorrhea, oligomenorrhea, erectile dysfunction

Investigations
- serum PRL, TSH, liver enzyme tests, creatinine
- macroprolactin level in patients with hyperprolactinemia but no symptoms of prolactin excess
- MRI of the sella turcica when a secondary cause is not identified or when prolactin levels suggest that there may be underlying tumoural hyperprolactinemia

Treatment
- first line: long-acting dopamine agonist: bromocriptine, cabergoline, or quinagolide
- surgery ± radiation (rare)
- prolactin-secreting tumours are often slow-growing; treatment may not be necessary in the setting of small tumours associated with hyperprolactinemia that does not result in hypogonadism or bothersome galactorrhea
- if medication-induced, consider stopping medication if possible
- in certain cases if microprolactinoma and not planning on becoming pregnant, may consider OCP

Thyroid Stimulating Hormone

- see Thyroid, E21
Adrenocorticotropic Hormone

• see Adrenal Cortex, E30

Luteinizing Hormone and Follicle Stimulating Hormone

HYPOGONADOTROPIC HYPOGONADISM
• hypogonadism due to impaired release of FSH and LH

Etiology
• primary/congenital: Kallmann syndrome, CHARGE syndrome, GnRH insensitivity
• secondary: CNS or pituitary tumours, pituitary apoplexy, brain/pituitary radiation, drugs (GnRH agonists/antagonists, glucocorticoids, narcotics, chemotherapy, drugs causing hyperprolactinemia), functional deficiency due to another cause (hyperprolactinemia, chronic systemic illnesses, eating disorders, hypothyroidism, DM, Cushing's disease), systemic diseases (hemochromatosis, sarcoidosis, histiocytosis)

Clinical Features
• hypogonadism, amenorrhea, erectile dysfunction (see Urology, U32), loss of body hair, fine skin, testicular atrophy, and failure of pubertal development

Treatment
• combined FSH/LH hormone therapy, human chorionic gonadotropin (hCG), rFSH, or pulsatile GnRH analogue if fertility desired
• symptomatic treatment with estrogen/testosterone

HYPERGONADOTROPIC HYPOGONADISM
• hypogonadism due to impaired response of the gonads to FSH and LH

Etiology
• congenital:
  - chromosomal abnormalities (Turner’s syndrome, Klinefelter syndrome, XX gonadal dysgenesis)
  - enzyme defects (17α-hydroxylase deficiency, 17,20-lyase deficiency)
  - gonadotropin resistance (Leydig cell hypoplasia, FSH insensitivity, pseudohypoparathyroidism type 1A)
• acquired:
  - gonadal toxins (chemotherapy, radiation)
  - drugs (glucocorticoids, antiandrogens, opioids, alcohol)
  - infections (STIs, mumps)
  - gonadal failure in adults (androgen decline and testicular failure in men, premature ovarian failure and menopause in women)

Clinical Features
• amenorrhea, erectile dysfunction (see Urology, U33), loss of body hair, fine skin, testicular atrophy, failure of pubertal development, low libido, and infertility

Treatment
• hormone replacement therapy consisting of androgen (for males) and estrogen (for females) administration

Antidiuretic Hormone

DIABETES INSIPIDUS

Definition
• disorder of ineffective ADH (decreased production or peripheral resistance) resulting in passage of large volumes of dilute urine

Etiology and Pathophysiology
• central DI: insufficient ADH due to pituitary surgery, tumours, idiopathic/autoimmune, stalk lesion, hydrocephalus, histiocytosis X, trauma, familial central DI
• nephrogenic DI: collecting tubules in kidneys resistant to ADH due to drugs (e.g. lithium), hypercalcemia, hypokalemia, chronic renal disease, hereditary nephrogenic DI
• psychogenic polydipsia and osmotic diuresis must be ruled out

Clinical Features
• passage of large volumes of dilute urine, polydipsia, and dehydration; hypernatremia can develop with inadequate water consumption or secondary to an impaired thirst mechanism

Diagnostic Criteria
• fluid deprivation will differentiate true DI (high urine output persists, urine osmolality < plasma osmolality) from psychogenic DI (psychogenic polydipsia)
• response to exogenous ADH (DDAVP) will distinguish central from nephrogenic DI
Treatment
- central DI: first line = desmopressin; second line = chlorpropamide, thiazides, NSAIDs and carbamazepine
- nephrogenic DI: solute restriction, thiazide diuretics

SYNDROME OF INAPPROPRIATE ADH SECRETION
Diagnostic Criteria
- 1) hyponatremia (serum Na+ <135 mEq/L) with 2) plasma hypo-osmolality (<275 mOsm/kg), 3) urine Na+ concentration >40 mEq/L, 4) urine osmolality >100 mOsm/kg, 5) euvoelema (no edema) and 6) absence of adrenal, renal, or thyroid insufficiency

Etiology and Pathophysiology
- stress (pain, nausea, post-surgical)
- malignancy (lung, pancreas, lymphoma)
- CNS disease (inflammatory, hemorrhage, tumour, Guillain-Barré syndrome)
- respiratory disease (tuberculosis, pneumonia, empyema)
- drugs (SSRIs, vincristine, chlorpropamide, cyclophosphamide, carbamazepine, nicotine, morphine, DDAVP, oxytocin)

Clinical Features
- symptoms of hyponatremia: headaches, nausea, vomiting, muscle cramps, tremors, cerebral edema if severe (confusion, mood swings, hallucinations, seizures, coma)

Treatment
- goal is to increase serum sodium
- treat underlying cause, fluid restriction (800-1000 mL/d), vasopressin receptor antagonists (e.g. tolvaptan, conivaptan), demeclocycline (antibiotic with anti-ADH properties, rarely-used), and furosemide

Pituitary Pathology
PITUITARY ADENOMA (see Neurosurgery, NS14)

Clinical Features
- local mass effects
  - visual field defects (bitemporal hemianopsia due to compression of the optic chiasm), diplopia (due to oculomotor nerve palsies is rare), headaches; increased ICP is rare
- hypofunction
- hypopituitarism
- hyperfunction
  - PRL (galactorrhoea, GH (acromegaly in adults, gigantism in children), ACTH (Cushing's disease = Cushing's syndrome caused by a pituitary tumour)
  - tumours secreting LH, FSH, and TSH are rare

Investigations
- radiological evaluation (MRI is imaging procedure of choice)
- formal visual field testing for tumours compressing the optic chiasm
- hypothalamic-pituitary hormonal function

HYPOPITUITARISM
Etiology (The Eight I's)
- Invasive
  - pituitary tumours, craniopharyngioma, cysts (Rathke's cleft, arachnoid, or dermoid), metastases
- Infarction/hemorrhage
  - Sheehan's syndrome (pituitary infarction due to excessive post-partum blood loss and hypovolemic shock)
  - pituitary apoplexy (acute hemorrhage/infarction of a pituitary tumour; presents with sudden loss of pituitary hormones, severe headache, and altered level of consciousness; can be fatal if not recognized and treated early)
- Infiltrative/inflammatory
  - sarcoidosis, hemochromatosis, histiocytosis
- Infectious
  - syphilis, tuberculosis, fungal (histoplasmosis), parasitic (toxoplasmosis)
- Injury
  - severe head trauma
- Immunologic
  - autoimmune destruction
- Iatrogenic
  - following surgery or radiation
- Idiopathic
  - familial forms, congenital midline defects
Clinical Features
• symptoms depend on which hormone is deficient:
  • ACTH: fatigue, weight loss, hypoglycemia, anemia, hyponatremia, failure to thrive and delayed puberty in children
  • GH: short stature in children, adults exhibit increased fat and decreased lean body mass, decreased BMD, fatigue
  • TSH: tiredness, cold intolerance, constipation, weight gain
  • LH and FSH: oligo- or amenorrhea, infertility, decreased facial/body hair and muscle mass in men, erectile dysfunction, delayed puberty
  • Prolactin: inability to breastfeed
  • ADH: symptoms of diabetes insipidus (extreme thirst, polydipsia, hypernatremia)
  • Oxytocin: usually asymptomatic – only needed during labour and breastfeeding

Investigations
• triple bolus test
  • stimulates release of all anterior pituitary hormones in normal individuals
  • rapid sequence of IV infusion of insulin, GnRH, and TRH
  • insulin (usual dose 0.1 unit/kg of human regular insulin) → hypoglycemia → increased GH and ACTH/cortisol
  • GnRH (100 µg IV push) → increased LH and FSH
  • TRH (200 µg IV push over 120 s) → increased TSH and PRL (no longer available in Canada)
  • GnRH and TRH stimulation tests are very limited in their utility; the insulin tolerance test is the only truly useful test in the triple bolus assessment

Thyroid Hormones

Synthetic Function of Thyroid Gland
• the synthesis of thyroid hormones T₃ (thyroxine) and T₄ (triiodothyronine) by the thyroid gland involves trapping and oxidation of iodide, iodination of thyroglobulin, proteolysis of thyroglobulin, and release of T₃ and T₄
  • more than 90% of thyroid hormone secreted by the thyroid is T₄
  • free T₄ (0.02%) and free T₃ (0.3%) represent the hormonally active fraction of thyroid hormones
  • the remaining fraction is bound to thyroxine binding globulin (TBG), albumin and transthyretin, and is biologically inactive
  • T₄ is more biologically active (approximately 4x as potent as T₃), but T₃ is present in the blood in smaller quantities and has a shorter half-life compared to T₄
  • 85% of T₄ is converted to T₃ or reverse T₃ (RT₃) in the periphery by deiodinase enzymes
  • RT₃ is metabolically inactive but produced in times of stress to decrease metabolic activity

Extra-Thyroidal Factors Impacting Thyroid Hormone Homeostasis: A Review
JRM 2015;4(1):40-49
• Most peripheral thyroid metabolism occurs in the liver and the kidneys, thus severe liver disease and CKD can significantly alter T₃:T₄ ratio.
• Alcohol dependence results in hypothalamic-pituitary-thyroid axis dysfunction demonstrated by decreased TSH, T₄, and T₃ levels.
• Smoking is associated with lower TSH levels in a dose-dependent manner: with heavy smoking (8-12 cigarettes/d) having more TSH suppression than light smokers (<4 cigarettes/d).
• Heavy metal exposure including lead, mercury, and cadmium has been shown to alter thyroid hormone function and peripheral metabolism.
• most of the plasma T3 pool is derived from the peripheral conversion of T4
• calcitonin, a peptide hormone, is also produced in the thyroid, by the parafollicular cells or C cells
  • calcitonin functions by inhibiting osteoclast activity and increasing renal calcium excretion

Role of Thyroid Hormones
• thyroid hormones act primarily through modifying gene transcription by binding to nuclear receptors
• action of these hormones is diffuse, affecting nearly every organ system
• thyroid hormones have different tissue-specific effects determined by the expression of the types of thyroid receptor isofoms and the local production of T3
• they increase the basal metabolic rate including: increased Na+/K+ ATPase activity, increased O2 consumption, increased respiration, heat generation, and increased cardiovascular activity
• when present at higher than normal levels it potentiates the actions of GH, catecholamines (epinephrine, norepinephrine), glucagon and cortisol, resulting in increased gluconeogenesis, ketogenesis and proteolysis, mimicking what happens in starvation
• it increases sensitivity to catecholamines, by up-regulating their receptors, but does not alter their blood concentrations
• thyroid hormone is required for normal growth in the fetus and child, including the central nervous system, via stimulation of GH release, in synergism with cortisol

Regulation of Thyroid Function
• extrathyroid
  • stimulation of thyroid by TSH, epinephrine, prostaglandins (cAMP stimulators T3; negatively feeds back on anterior pituitary to inhibit TSH and on hypothalamus to inhibit TRH
• T3 intrathyroid (autoregulation)
  • synthesis (Wolf-Chaikoff effect, Jod-Basedow effect)
  • there is varying thyroid sensitivity to TSH in response to iodide availability
  • increased ratio of T3 to T4 in iodide deficiency
  • increased activity of peripheral 5’ deiodinase in hypothyroidism increases T3 production despite low T4 levels

Tests of Thyroid Function and Structure

TSH
• third generation TSH is the best test for assessing thyroid function
• hyperthyroidism
  • primary: TSH is low because of negative feedback from increased levels of circulating T3 and T4
  • secondary: increased TSH results in increased T3 and T4
• hypothyroidism
  • primary: increased TSH (most sensitive test) because of less negative feedback from T3 and T4
  • secondary: TSH is low or normal with variable response to TRH depending on the site of the lesion (pituitary or hypothalamic)

Free T3 and Free T4
• standard assessment of thyroid function measures TSH and, if necessary, free T4. Free T3 should only be measured in the small subset of patients with hyperthyroidism and suspected T3 toxicosis. TSH would be suppressed, free T4 normal, and free T3 elevated

Thyroid Autoantibodies
• thyroglobulin antibodies (TgAb), anti-thyroid peroxidase antibodies (TPOAb), and TSH receptor antibodies (TRAb) of the blocking variety are increased in Hashimoto’s disease; normal variant in 10–20% of individuals
• TRAb of the stimulating variety are also referred to as thyroid stimulating immunoglobulins (TSI) and cause Graves’ disease. However, both TRAb receptor blocking and stimulating antibodies are seen in patients with Graves’ disease

Plasma Thyroglobulin
• used to monitor for residual thyroid tissue post-thyroidectomy, e.g. tumour marker for thyroid cancer recurrence
• detectable or elevated levels may suggest persistent, recurrent, or metastatic disease

Serum Calcitonin
• not routinely done to investigate thyroid nodules
• ordered if suspicion of medullary thyroid carcinoma e.g. in patients with a thyroid nodule and suspected or confirmed MEN IIa or IIb syndromes or those who have a pathogenic mutation in RET
• used to monitor for residual or recurrent medullary thyroid cancer

Does this Patient have a Goitre?
From The Rational Clinical Examination
Study: Systematic review of articles assessing the accuracy and precision of the clinical exam in the diagnosis of a goitre.
Results: Clinical diagnosis was based on degree of lateral prominence, visibility, and palpability of the thyroid gland. No evidence exists to support the superiority of any one method.
The combined results of 4 studies detail the predictive utility of assessing grades of thyroid gland weight.

<table>

</tr>
</tbody>
</table>

Alternatively, defining a goitre as mass larger than the distal phalanx of the thumb has been shown to have an LR+ of 3.9 (95% CI 2.5-5.9) and LR- of 0.80 (95% CI 0.24-0.37) in children, and an LR+ of 4.7 (95% CI 3.6-6.3) and LR- of 0.08 (95% CI 0.02-0.37) for the presence of a goitre.
Conclusions: Use of weight of thyroid tissue is an appropriate method of diagnosing a goitre, while comparing the size of thyroid mass to the distal phalanx of the thumb may be a useful alternative.
Thyroid Imaging/Scans
- normal gland size 15-20 g (estimated by palpation)
- thyroid U/S
  - to measure size of gland, characterize thyroid nodules, facilitate fine needle aspirate biopsy (FNAB)
  - exception is hyperthyroid patients where use of a radioisotope thyroid scan and RAIU (see below) permits identification of hyperfunctioning nodules which generally do not need to be biopsed
  - radioisotope thyroid scan (Technetium-99) only if 1) one or more thyroid nodule(s) and 2) patient is hyperthyroid to determine whether nodules are hot (functioning > excess thyroid hormone production) or cold (non-functioning)
- hot nodule > very low chance malignancy; treat hyperthyroidism
- cold nodule > further workup required (U/S, then FNAB if concerning sonographic features)
- radioactive iodine uptake (RAIU)
  - test of function: order if patient is thyrotoxic
  - RAIU measures the turnover of iodine by thyroid gland in vivo
  - if ↑ uptake (e.g. incorporated), gland is overactive (hyperthyroid)
  - if ↓ uptake (e.g. not incorporated), gland is leaking thyroid hormone (e.g. thyroiditis), exogenous thyroid hormone use, or excess iodine intake (e.g. amiodarone or contrast dye, which has high iodine content)
- see Figure 9, Thyroid Hormone Synthesis, E21 for further information regarding the utility of these scans

Thyroid Biopsy
- fine needle aspiration (FNA) for cytology
  - differentiates between benign and malignant disease
  - best done under U/S guidance
  - accuracy decreased if nodule is greater than 50% cystic, or if nodule located posteriorly in the gland

Thyrotoxicosis

Definition
- clinical, physiological, and biochemical findings in response to elevated thyroid hormone

Epidemiology
- 1% of general population have hyperthyroidism
- F:M = 5:1
Etiology and Pathophysiology

</tr>
</tbody>
</table>

Treatment

- β-blockers for control of adrenergic symptoms
- antithyroidals (thionamides): propylthiouracil (PTU) or methimazole (MMI); MMI recommended (except in first trimester pregnancy); block thyroid hormone production
- antithyroidals to prepare patients with endogenous hyperthyroidism for surgery, for patients with Graves’ disease, and for patients with toxic nodules who do not wish to have definitive treatment with radioactive iodine or surgery
- radioactive iodine thyroid ablation for Graves’ disease and toxic nodules/adenoma
- surgery in the form of hemi, subtotal, or complete thyroidectomy for toxic nodules
- surgery in the form of total or near total thyroidectomy for Graves’ disease
Graves’ Disease

Definition
- an autoimmune disorder characterized by autoantibodies that stimulate the TSH receptor leading to hyperthyroidism

Epidemiology
- most common cause of hyperthyroidism
- occurs at any age with peak in 3rd and 4th decade
- F:M = 7:1, 1.5-2% of U.S. women
- familial predisposition: 15% of patients have a close family member with Graves’ disease and 50% have family members with positive circulating antibodies
- association with HLA-B8 and DR3
- may be associated with other autoimmune disorders (e.g. pernicious anemia, Hashimoto’s disease)

Etiology and Pathophysiology
- autoimmune disorder due to breakdown in thyroid tolerance likely due to a combination of factors including autoreactive B lymphocytes and an imbalance favouring a Th2 vs Th1 immune response
- B lymphocytes produce thyroid-stimulating immunoglobulin (TSI) that binds and stimulates the TSH receptor on the thyroid gland
- immune response can be triggered by postpartum state, iodine excess, viral or bacterial infections, glucocorticoid withdrawal
- ophthalmopathy (thyroid associated orbitopathy) is a result of increased connective and extraocular muscle tissue volume due to inflammation and accumulation of glycosaminoglycans, stimulated by TSI, that increase osmotic pressure within the orbit; this leads to fluid accumulation and forward displacement of the eyeball
- dermopathy (pretibial or localized myxedema) may be related to cutaneous glycosaminoglycan deposition

Clinical Features
- signs and symptoms of thyrotoxicosis
- diffuse goitre ± thyroid bruit secondary to increased blood flow through the gland
- ophthalmopathy: proptosis, diplopia, conjunctival injection, corneal abrasions, periorbital puffiness, lid lag, decreased visual acuity (plus signs of hyperthyroidism: lid retraction, characteristic stare)
- dermopathy (rare): pretibial myxedema: thickening of dermis that manifests as non-pitting edema
- acropachy: clubbing and thickening of distal phalanges

Investigations
- low TSH
- increased free T4 (and/or increased T3)
- positive for TRAb (sensitivity and specificity of third-generation TRAb tests that are available currently is over 95 percent allowing their use for determining the etiology of hyperthyroidism)
- increased radioactive iodine (I-131) uptake
- homogeneous uptake on thyroid scan

Treatment
- treatment for Graves’ disease includes thionamides, radiodine (RAI), or surgery. These treatment options are not mutually exclusive. Patients who start with medical management, may eventually require a definitive treatment with RAI or surgery
- thionamides (antithyroid medications): propylthiouracil (PTU) or methimazole (MMI)
  - PTU and MMI inhibit thyroid hormone synthesis by inhibiting peroxidase-catalyzed reactions, thereby inhibiting organification of iodide, blocking the coupling of iodytrosines
  - PTU also inhibits peripheral deiodination of T4 to T3
  - treat for approximately 12-18 mo aiming for a normal TSH and TRAb prior to consideration of treatment discontinuation
  - small goitre, mild hyperthyroidism, and low TRAb titres are good predictors for long-term remission with medical therapy
  - remission (normal thyroid indices one year after discontinuation of PTU or MMI) rates range between 20-30% following 12-18 mo of antithyroid medication
  - major side effects: hepatotoxicity (cholestasis, hepatitis), agranulocytosis, vasculitis
  - minor side effects: minor rash, pruritus
  - MMI preferred vs. PTU due to longer duration of action (once daily dosing for most), more rapid resolution of hyperthyroidism, and lower incidence of side effects
  - in pregnancy: use PTU during first 16 weeks of pregnancy and MMI after. MMI is contraindicated in the first trimester due to risk of aplasia cutis; MMI is preferred in the second and third trimester due to the potential risk of hepatotoxicity with PTU in the second and third trimesters
  - symptomatic treatment with β-blockers
  - thyroid ablation with radioactive I-131 if PTU or MMI trial does not produce disease remission or patient prefers definitive treatment with RAI
    - high incidence of hypothyroidism after I-131 requiring lifelong thyroid hormone replacement
    - contraindicated in pregnancy
    - may worsen ophthalmopathy
  - total or near total thyroidectomy (indicated for large goitres, suspicious nodule for cancer, or if patient is intolerant to thionamides and refusing RAI ablation)
    - risks: hypoparathyroidism and vocal cord palsy

Caution with Thionamides
- These drugs are effective in controlling hyperthyroidism and induce permanent remission in 20-30% of patients with Graves’ disease. They inhibit thyroid hormone synthesis. They are most often employed to achieve a euthyroid state before definitive treatment. Adverse effects include teratogenicity, agranulocytosis, hepatotoxicity, and ANCA-positive vasculitis

Glucocorticoids
- have been useful in the treatment of severe Graves hyperthyroidism and thyroid storm, by inhibiting the conversion of peripheral T4 to T3
- Lithium is also used to treat Graves’ hyperthyroidism. It acts by blocking thyroid hormone release, but its toxicity has limited its use in practice
• ophthalmopathy/orbitopathy
• smoking cessation is important
• prevent drying of eyes and ulceration of cornea by using artificial tears during the day and lubricants at night
• high dose prednisone or IV methylprednisolone in severe cases
• high dose glucocorticoids preferably IV as well as potential orbital decompression surgery for sight threatening orbitopathy
• orbital radiation, surgical decompression

Prognosis
• course involves remission and exacerbation unless gland is destroyed by radioactive iodine or surgery
• total and subtotal thyroidectomy are rapid cures with low risk of recurrence (2% and 10%, respectively); risks include permanent hypothyroid and potential of damage to laryngeal nerve
• radioactive iodine is less invasive than surgery, but also results in permanent hypothyroid and requires precautions in contacts several days after treatment
• medical therapy with thionamides is not invasive, but has high recurrence rate at ~50%
• lifetime follow-up needed

Subacute Thyroiditis (Thyrotoxic Phase)

• there are two main types: painful (DeQuervain’s) and painless (silent)

Toxic Adenoma/Toxic Multinodular Goitre

Etiology and Pathophysiology
• autonomous thyroid hormone production from a functioning adenoma that is hypersecreting T3 and T4
• may be singular (toxic adenoma) or multiple (toxic multinodular goitre [Plummer’s disease])

Clinical Features
• multinodular goitre
• tachycardia, heart failure, arrhythmia, weight loss, nervousness, weakness, tremor, and sweats
• seen most frequently in elderly people as opposed to Graves’ disease which is more common in younger individuals

Investigations
• low TSH, high T3 and T4
• thyroid scan with increased RAIU in nodule(s) and suppression of the remainder of the gland

Treatment
• use high dose radioactive iodine (I-131) to ablate hyperfunctioning nodules
• β-blockers often necessary for symptomatic treatment prior to definitive therapy
• surgical excision may also be used as 1st line treatment
initiate therapy with PTU or MMI to attain euthyroid state in individuals who do not wish to have definitive treatment of their disease, in preparation for thyroidectomy, and prior to RAI in patients at risk for complications due to exacerbation of hyperthyroidism following RAI such as the elderly with cardiovascular disease.

### Thyrotoxic Crisis/Thyroid Storm

**Definition**
- medical emergency – acute exacerbation of all of the symptoms of thyrotoxicosis presenting in a life-threatening state secondary to uncontrolled hyperthyroidism!
- rare, but serious with mortality rate between 10-30%

**Etiology and Pathophysiology**
- often precipitated by infection, trauma, or surgery in a hyperthyroid patient

**Differential Diagnosis**
- sepsis, pheochromocytoma, malignant hyperthermia, drug overdose, neuroleptic malignant syndrome

**Clinical Features**
- hyperthyroidism
- extreme hyperthermia (≥40°C), tachycardia, vomiting, diarrhea, hepatic failure with jaundice, atrial fibrillation, congestive heart failure
- central nervous system manifestations including agitation, delirium, psychosis, lethargy, seizures, coma

**Laboratory Investigations**
- increased free T3 and T4, undetectable TSH
- ± anemia, leukocytosis, hyperglycemia, hypercalcemia, elevated LFTs

**General Measures**
- fluids, electrolytes, and vasopressor agents should be used as indicated
- a cooling blanket and acetaminophen can be used to treat the pyrexia
- propranolol or other β-blockers that additionally decrease peripheral conversion of T4 → T3 can be used, but should be used with caution in patients with decompensated heart failure as it may worsen condition

**Specific Measures**
- PTU is the anti-thyroid drug of choice and is used in high doses (200 mg q4h)
- give iodide, which acutely inhibits the release of thyroid hormone, 1 h after the first dose of PTU is given:
  - Sodium iodide 1 g IV drip over 12 h q12h
  - Lugol's solution 10 drops q8h
  - Potassium iodide (SSKI) 5 drops q6h
- hydrocortisone 100 mg IV q8h or dexamethasone 2-4 mg IV q6h for the first 24-48 h; inhibits peripheral conversion of T4 → T3

### Hypothyroidism

**Definition**
- clinical syndrome caused by cellular responses to insufficient thyroid hormone production

**Epidemiology**
- 2-3% of general population
- F:M = 10:1
- 10-20% of women >50 have subclinical hypothyroidism (normal T4, TSH mildly elevated)
- iodine deficiency most common cause worldwide, but not in North America

**Etiology and Pathophysiology**
- primary hypothyroidism (90%)
  - inadequate thyroid hormone production secondary to intrinsic thyroid defect
  - iatrogenic: post-ablative (I-131 or surgical thyroidectomy)
  - autoimmune: Hashimoto's thyroiditis
  - hypothyroid phase of subacute thyroiditis
  - drugs: goitrogens (iodine), PTU, MMI, lithium
  - infiltrative disease (progressive systemic sclerosis, amyloid)
  - iodine deficiency
  - congenital (1/4000 births)
  - neoplasia

---

**Factors Affecting Gastrointestinal Absorption of Levothyroxine: A Review**

Clin Ther 2017;39(2):378-403

- GI disorders such as celiac disease, atrophic gastritis, lactose intolerance, or H. pylori infection may impede levothyroxine absorption.
- Drugs decreasing stomach acidity have been shown to significantly reduce exogenous thyroid hormone absorption from the GI tract. These include proton-pump inhibitors, H2 receptor antagonists, calcium carbonate, sucralfate and aluminum hydroxide.
- Iron citrate is shown to reduce intestinal absorption of levothyroxine.
- Foods, especially soybeans and coffee, have been shown to reduce absorption of levothyroxine significantly.
- Roughly 85% of levothyroxine is absorbed within 3h after administration of the drug. Thus, patients should be educated to take levothyroxine on an empty stomach at least one hour prior to eating breakfast.
• secondary hypothyroidism: pituitary hypothyroidism
  • insufficiency of pituitary TSH
• tertiary hypothyroidism: hypothalamic hypothyroidism
  • decreased TRH from hypothalamus (rare)
• peripheral tissue resistance to thyroid hormone (Refetoff syndrome)

</tr>
</tbody>
</table>

Treatment

• L-thyroxine (dose range: 0.05-0.2 mg PO OD ~1.6 µg/kg/d)
• elderly patients and those with CAD: start at 0.025 mg daily and increase gradually every 6 wk (start low, go slow)
• after initiating L-thyroxine, TSH needs to be evaluated in 6 wk; dose is adjusted until TSH returns to normal reference range
• once maintenance dose achieved, follow-up TSH with patient annually
• secondary/tertiary hypothyroidism monitor via measurement of free T4 (TSH is unreliable in this setting)

CONGENITAL HYPOTHYROIDISM

• see Pediatrics, P29

Hashimoto’s Thyroiditis

Definition

• most common form of primary hypothyroidism in North America
• chronic autoimmune thyroiditis characterized by both cellular and humoral factors in the destruction of thyroid tissue
• two major forms: goitrous and atrophic; both forms share same pathophysiology but differ in the extent of lymphocytic infiltration, fibrosis, and thyroid follicular cell hyperplasia
• goitrous variant usually presents with a small, rubbery goitre and euthyroidism, then hypothyroidism becomes evident
  • associated with fibrosis
• atrophic variant patients are hypothyroid from the start associated with thyroid lymphoma

Etiology and Pathophysiology

• defect in clone of T-suppressors leads to cell-mediated destruction of thyroid follicles
• B lymphocytes produce antibodies against thyroid components including thyroglobulin, thyroid peroxidase, TSH receptor, Na+/I– symporter

Risk Factors

• M:F = 7:1
• genetic susceptibility: increased frequency in patients with Down’s syndrome, Turner’s syndrome, certain HLA alleles, cytotoxic T-lymphocyte-associated protein 4 (CTLA-4)
• family Hx or personal Hx of other autoimmune diseases
• cigarette smoking
• high iodine intake

Investigations

• high TSH, low T4 (not necessary to measure T3 as it will be low as well)
• presence of anti-thyroid peroxidase (TPOAb) and thyroglobulin antibodies (TgAb) in serum

Treatment

• if hypothyroid, replace with L-thyroxine (analog of T4)
**Myxedema Coma**

**Definition**
- medical emergency – severe hypothyroidism complicated by trauma, sepsis, cold exposure, MI, inadvertent administration of hypnotics or narcotics, and other stressful events
- rare; high level of mortality (up to 40%, despite therapy)

**Clinical Features**
- hallmark symptoms of decreased mental status and hypothermia
- hyponatremia, hypotension, hypoglycemia, bradycardia, hypoventilation, and generalized non-pitting edema often present

**Investigations**
- decreased T4, increased TSH, decreased glucose
- check ACTH and cortisol for evidence of adrenal insufficiency

**Treatment**
- aggressive and immediate treatment required
- ABCs: ICU admission
- corticosteroids (for risk of concomitant adrenal insufficiency): hydrocortisone 100 mg q8h
- L-thyroxine 0.2-0.5 mg IV loading dose, then 0.1 mg IV OD until oral therapy tolerated; also consider T3 therapy
- supportive measures: mechanical ventilation, vasopressor drugs, passive rewarming, IV dextrose, fluids if necessary (risk of overload)
- monitor for arrhythmia

**Sick Euthyroid Syndrome**

**Definition**
- changes in the regulation of the hypothalamic-pituitary-thyroid axis and thyroid hormone metabolism and transport amongst patients with severe illness, trauma, surgery, or starvation
- not due to intrinsic thyroid, pituitary, or hypothalamic disease
- initially low free T3 may be followed by low TSH and if severe illness low free T4
- with recovery of illness, TSH may become transiently high

**Pathophysiology**
- abnormalities include alterations in:
  - peripheral transport and metabolism of thyroid hormone
  - regulation of TSH secretion
  - may be protective during illness by reducing tissue catabolism

**Labs**
- initially decreased free T3 followed by decreased TSH and finally decreased free T4

**Treatment**
- treat the underlying disease; thyroid hormone replacement has not shown to be beneficial
- thyroid function tests normalize once patient is well (initially with a transient increase in TSH)

**Non-Toxic Goitre**

**Definition**
- generalized enlargement of the thyroid gland in a euthyroid individual that does not result from inflammatory or neoplastic processes

**Pathophysiology**
- the appearance of a goitre is more likely to present during adolescence, pregnancy, and lactation due to increased thyroid hormone requirements
  - early stages: goitre is usually diffuse
  - later stages: multinodular non-toxic goitre with nodule, cyst formation and areas of ischemia, hemorrhage, and fibrosis

**Etiology**
- iodine deficiency or excess
- goitrogens: brassica vegetables (e.g. turnip, cassava)
- drugs: iodine, lithium, para-aminosalicylic acid
- any disorder of hormone synthesis with compensatory growth
- peripheral resistance to thyroid hormone

**Treatment**
- remove goitrogens
- radiiodine therapy (need very high doses given low iodine uptake, used as last resort)
- suppression with L-thyroxine (rarely done)
- surgery may be necessary for severe compressive symptoms; however, these patients are often asymptomatic
Complications
- compression of neck structures causing stridor, dysphagia, pain, and hoarseness of voice
- multinodular goitre may become autonomous leading to toxic multinodular goitre and hyperthyroidism

Thyroid Nodules

Definition
- discrete lesion that and be distinguished sonographically from the rest of the thyroid parenchyma
- nodules found incidentally on ultrasound suggests a prevalence of 19-67%

Etiology
- benign tumours (e.g. follicular adenoma)
- thyroid malignancy
- hyperplastic area in a multinodular goitre
- cyst: true thyroid cyst, area of cystic degeneration in a multinodular goitre

Investigations

Thyroid Malignancies
- see Otolaryngology, OT37

Adrenal Cortex

Adrenocorticotropic Hormone
- a polypeptide (cleaved from prohormone POMC), secreted in a pulsatile fashion from the anterior pituitary with diurnal variability (peak: 0200-0400 h; trough: 1800-2400 h)
- secretion regulated by corticotropin-releasing hormone (CRH) and arginine vasopressin (AVP)
- stimulates growth of adrenal cortex and release of glucocorticoids, androgens and, to a very limited extent, mineralocorticoids
- ACTH can directly bind to MSH receptors on melanocytes, enhancing melanogenesis

Adrenocortical Hormones

Aldosterone
- a mineralocorticoid which regulates extracellular fluid (ECF) volume through Na⁺ (and Cl⁻) retention and K⁺ (and H⁺) excretion (stimulates distal tubule Na⁺/K⁺ ATPase)
- regulated by the renin-angiotensin-aldosterone system and by hyperkalemia
- negative feedback to juxtaglomerular apparatus (JGA) by long loop (aldosterone ↑ volume expansion) and short loop (angiotensin II ↑ peripheral vasoconstriction)
Cortisol
- a glucocorticoid, regulated by the HPA axis
- involved in the regulation of metabolism
- supports blood pressure and vasomotor tone
- also involved in behavioural regulation and immunosuppression

**Table 22. Physiological Effects of Glucocorticoids**

<table>

</tr>
<tr>
<td>Stimulate leukocytosis and lymphopenia</td>
<td>Inhibit growth hormone axis*</td>
</tr>
<tr>
<td>Increase cardiac output, vascular tone, Na⁺ retention</td>
<td>Inhibit reproductive axis*</td>
</tr>
<tr>
<td>Increase PTH release, vascular tone, Na⁺ retention</td>
<td>Inhibit vitamin D3 and inhibit calcium uptake</td>
</tr>
</tbody>
</table>

*Typically only occurs with cortisol excess*

Androgens
- sex steroids regulated by ACTH; primarily responsible for adrenarche (growth of axillary and pubic hair)
- principal adrenal androgens are: dihydroepiandrosterone (DHEA), androstenedione, and 11-hydroxyandrostenedione
- proportion of total androgens (adrenal to gonadal) increases in old age
**Adrenocortical Functional Workup**

**STIMULATION TEST**
- **purpose**: diagnosis of hormone deficiencies
- **method**: measure target hormone after stimulation with tropic (pituitary) hormone

**Tests of Glucocorticoid Reserve**
- Cosyntropin (ACTH analogue) Stimulation Test
  - administer 250 µg cosyntropin IV/IM, and measure plasma cortisol levels before and 30 and 60 min after administration
  - physiologic response: stimulated plasma cortisol of >1500 nmol/L (>18 µg/L) at 30 or 60 min
  - inappropriate response: inability to stimulate increased plasma cortisol
- insulin tolerance test is the gold standard test used to diagnose adrenal insufficiency (see Pituitary Gland, E16)

**SUPPRESSION TESTS**
- **purpose**: diagnosis of hormone hypersecretion
- **method**: measure target hormone after suppression of its tropic (pituitary) hormone

1. **Tests of Pituitary-Adrenal Suppressibility**
   - Dexamethasone (DXM) Suppression Test
     - principle: DXM suppresses pituitary ACTH, plasma cortisol should be lowered if HPA axis is normal
     - Screening Test: Overnight DXM Suppression Test
       - oral administration of 1 mg DXM at midnight, then measure plasma cortisol levels the following day at 8 AM
       - physiologic response: plasma cortisol <50 nmol (<1.8 µg/dL)
       - inappropriate response: failure to suppress plasma cortisol
       - false positive results due to obesity, depression, alcoholism, medications inducing the metabolism of dexamethasone
     - Confirmatory Test: other testing is used to confirm the diagnosis, such as:
       - 24 h urine free cortisol (shows overproduction of cortisol)
       - midnight salivary cortisol (if available), shows lack of diurnal variation
         - inappropriate response: remains high (normally will be low at midnight)

2. **Tests of Mineralocorticoid Suppressibility**
   - multiple medications interfere with the interpretation of screening and confirmatory tests for primary aldosteronism and these may need to be held prior to testing
   - positive screen test for primary aldosteronism is elevated aldosterone:renin ratio in the presence of a low renin and high aldosterone and an andosterone ≥416 pmol/L
   - confirmation of primary aldosteronism requires lack of aldosterone suppression: with expansion of extracellular fluid volume (ECFV), plasma aldosterone should be lowered
   - ECFV Expansion with Normal Saline (NS)
     - IV infusion of 500 mL/h of NS for 4 h, then measure plasma aldosterone levels
       - plasma aldosterone >277 pmol/L is consistent with primary hyperaldosteronism, <140 pmol/L is normal
       - inappropriate response: failure to suppress plasma aldosterone

**Mineralocorticoid Excess Syndromes**

**Definition**
- primary aldosteronism (PA): excess aldosterone production (intra-adrenal cause) (previously called hyperaldosteronism)
- secondary aldosteronism (SA): aldosterone production in response to excess RAAS (extra-adrenal cause)

**Etiology**
- primary hyperaldosteronism
  - aldosterone-producing adrenal adenoma (Conn’s syndrome)
  - bilateral or idiopathic adrenal hyperplasia
  - glucocorticoid-remediable aldosteronism
  - aldosterone-producing adrenocortical carcinoma
  - unilateral adrenal hyperplasia
  - ectopic aldosterone-producing tumours
  - familial hyperaldosteronism (FH) types I-IV
- secondary hyperaldosteronism
Clinical Features

- HTN
- hypokalemia (+ mild hypernatremia), metabolic alkalosis
- normal K+, hyponatremia in SH (low effective circulating volume leads to ADH release)
- increased cardiovascular risk: LV hypertrophy, atrial fibrillation, stroke, and MI
- elevated risk of metabolic syndrome and T2DM
- fatigue, weakness, paresthesia, headache; severe cases present with tetany, intermittent paralysis (only if K+ <2.5 mEq/L)

Diagnosis

- investigate plasma aldosterone-renin ratio in patients with HTN and hypokalemia, drug resistant HTN, HTN and a first degree relative with primary aldosteronism, HTN and a family history of stroke in a first degree relative 40 yr, HTN and adrenal incidentaloma
- confirmatory testing for PA: aldosterone suppression test (demonstrate inappropriate aldosterone secretion with ECF volume expansion), adrenal vein sampling may be required to determine whether there is lateralization of aldosterone excess
- imaging: CT adrenal glands

<td>(140-277 indeterminant range)</td>
</tr>
</tbody>
</table>

Treatment

- inhibit action of aldosterone: spironolactone, eplerenone, triamterene, amiloride (act on sodium channels)
- surgical excision of adrenal adenoma
- secondary hyperaldosteronism: treat underlying cause
Cushing’s Syndrome

Definition
- results from chronic glucocorticoid excess (endogenous or exogenous sources)

Etiology
- ACTH-dependent (85%) – bilateral adrenal hyperplasia and cortisol hypersecretion due to:
  - ACTH-secreting pituitary adenoma (Cushing’s disease; 80% of ACTH-dependent)
  - ectopic ACTH-secreting tumour (e.g. small cell lung carcinoma, bronchial, carcinoid, pancreatic islet cell, pheochromocytoma, or medullary thyroid tumours)
- ACTH-independent (15%)
  - primary adrenocortical tumours: adenoma and carcinoma (uncommon)
  - bilateral adrenal nodular hyperplasia
- iatrogenic CS is probably more common than endogenous cortisol excess but is not frequently reported, it is of course ACTH-independent

Clinical Features
- symptoms: weakness, insomnia, mood disorders, impaired cognition, easy bruising, oligo-/amenorrhea, hirsutism, and acne (ACTH dependent)
- signs: central obesity, round face (“moon face”), supraclavicular and dorsal fat pads, facial plethora, proximal muscle wasting, purple abdominal striae, skin atrophy, acanthosis nigricans, HTN, hyperglycemia, osteoporosis, pathologic fractures, hyperpigmentation, hyperandrogenism (if ACTH-dependent)

Diagnosis
- complete a drug history to exclude exogenous sources for Cushing’s syndrome
- perform one of: 1) 24 h urine free cortisol (x2 samples), 2) low dose dexamethasone suppression test, or 3) late night salivary cortisol
- consider reasons for a false positive (e.g. pregnancy, depression, alcoholism, morbid obesity, poorly controlled DM)
- confirm with one of the remaining tests

Treatment
- adrenal
  - adenoma: unilateral adrenalectomy (curative) with glucocorticoid supplementation post-operatively, tapering slowly until HPA axis has recovered
  - carcinoma: adrenalectomy in patients with disease localized to the adrenal, adjunctive mitotane for individuals with high risk for current disease. Mitotane ± chemotherapy for patients with metastatic disease
  - medical treatment: ketoconazole to reduce cortisol, mitotane can be used – typically reserved for patients with malignant disease
- pituitary
  - transsphenoidal resection, with glucocorticoid supplementation post-operatively
  - if surgery delayed, contraindicated, or unsuccessful, consider medical management e.g. adrenal enzyme inhibitors (such as ketoconazole, metyrapone, and etomidate), glucocorticoid receptor antagonist (such as mifepristone)
  - ectopic ACTH tumour (paraneoplastic syndrome): usually bronchogenic cancer (poor prognosis) surgical resection, if possible; chemotherapy/radiation for primary tumour
  - medical treatment with mitotane or ketoconazole to reduce cortisol synthesis. Often required when surgery is delayed, contraindicated, or unsuccessful

Congenital Adrenal Hyperplasia
- see Pediatrics, P31
Hyperandrogenism

Definition
• state of having excessive secretion of androgens (DHEA, DHEA-sulfate, testosterone)

Etiology and Pathophysiology

Table 24. Etiology of Hyperandrogenism

Clinical Features

Females
• hirsutism
  • male pattern growth of androgen-dependent terminal body hair in women: back, chest, upper abdomen, face, linea alba
  • Ferriman-Gallwey scoring system is used to quantify severity of hirsutism (score of >8 is abnormal for white/black women, >9 abnormal for Mediterranean/Hispanic/Middle-Eastern women, >2 for Asian women)
• virilization
  • frontal balding, clitoromegaly, increased muscle mass, deepening of the voice
• amenorrhea, ▼ breast size, infertility

Males
• minimal effects on hair, muscle mass, etc.
• inhibition of gonadotropin secretion may cause reduction in: testicular size, testicular testosterone production, and spermatogenesis

Investigations
• testosterone, DHEA-S as a measure of adrenal androgen production
• LH/FSH (commonly in PCOS >2.5)
• 17-OH progesterone, elevated in CAH due to 21-OH deficiency; check on day 3 of menstrual cycle with progesterone level
• for virilization: CT/MRI of adrenals and ovaries (identify tumours)
• if PCOS, check blood glucose, lipids

Treatment
• discontinue causative medications
• antiandrogens, e.g. spironolactone
• oral contraceptives (increase sex hormone binding globulin, which binds androgens>estrogens; reduces ovarian production of androgens)
• surgical resection of tumour
• glucocorticoid ± mineralocorticoid if CAH confirmed
• treat specific causative disorders, e.g. tumours, Cushing’s, etc.
• cosmetic therapy (laser, electrolysis)

Conditions that do Not Represent True Hirsutism
• Androgen-independent hair (e.g. lanugo hair)
• Drug-induced hypertrichosis (e.g. phenytoin, diazoxide, cyclosporine, minoxidil)
• Topical steroid use
Adrenocortical Insufficiency

**Definition**
- state of inadequate cortisol and/or aldosterone production by the adrenal glands

**Etiology**

**PRIMARY (ADDISON’S DISEASE)**

Adapted from: Salvatori R. JAMA 2005;294:2481-2488

**Treatment**
- acute adrenal crisis – can be life-threatening
  - IV NS 1L within the first hour followed by continuous IV NS guided by patient requirements; add D5W if hypoglycemic
  - hydrocortisone 100 mg IV stat followed by 50 mg IV q6h
  - identify and correct precipitating factors
- maintenance
  - hydrocortisone 15-25 mg total daily dose, in 2-3 divided doses, highest dose in the AM
  - Florinef® (fludrocortisone, synthetic mineralocorticoid) 0.05-0.2 mg PO daily if mineralocorticoid deficient, increase dose of steroids 2-3 fold for a few days during moderate-severe illness (e.g. with vomiting, fever)
  - major stress (e.g. surgery, trauma) requires 150-300 mg hydrocortisone IV daily divided into 3 doses
  - medical alert bracelet and instructions for emergency hydrocortisone/dexamethasone IM/SC injection
Adrenal Medulla

Catecholamine Metabolism

- Catecholamines are synthesized from tyrosine in postganglionic sympathetic nerves (norepinephrine) and chromaffin cells of adrenal medulla (epinephrine).
- Broken down into metanephrines and other metabolites (VMA, HVA) and excreted in urine.

Pheochromocytoma/Paraganglioma

Definition

- Paragangliomas are rare neuroendocrine tumours that arise from the extra-adrenal autonomic paraganglia (small organs comprised of neuroendocrine cells that secrete catecholamines).
- Pheochromocytomas are catecholamine-secreting tumours derived from chromaffin cells of the adrenal gland.

Epidemiology

- Most commonly a single tumour of adrenal medulla.
- Rare cause of HTN (<0.2% of all hypertensives).

Etiology and Pathophysiology

- Pheochromocytomas and paragangliomas are the most inherited among neuroendocrine tumours.
- 30-40% cases are linked to germline mutations, including mutations in the RET, VHL, SDHx, NF1, and SDHA/SE2 genes.
- Pheochromocytomas and paragangliomas are divided into clusters: Cluster 1 - Pseudohypoxia subtype (FH, VHL/EPAS1-related), Cluster 2 - Kinase signalling group (HRAS), Cluster 3 - WNT signalling group (CSDE1, UBTB-MAML3 fusion).
- Most cases sporadic, 40% patients have the disease as part of a familial disorder in these patients, the tumours are more likely to be bilateral adrenal pheochromocytoma/paragangliomas.
- Hereditary forms present earlier than sporadic cases.
- Several familial disorders are associated with adrenal pheochromocytoma, all have autosomal dominant inheritance, e.g., multiple endocrine neoplasia type 2 (MEN2) - 50% frequency, von Hippel-Lindau (VHL) syndrome - 10-20% frequency, and less commonly, neurofibromatosis type 1 (NF1) - 0.1-5.7%.
- Tumours, via unknown mechanism, able to synthesize and release excessive catecholamines.

Clinical Features

- 50% suffer from paroxysmal HTN; the rest have sustained HTN.
- Classic triad (not found in most patients): episodic "pounding" headache, palpitations/tachycardia, diaphoresis.
- Other symptoms: tremor, anxiety, chest or abdominal pain, nausea and vomiting, visual blurring, weight loss, polyuria, polydipsia.
- Other signs: orthostatic hypotension, papilledema, hyperglycemia, dilated cardiomyopathy.
- Symptoms may be triggered by stress, exertion, anesthesia, abdominal pressure, certain foods (especially tyramine containing foods - such as aged/strong cheese and cured meats).

Investigations

- Urine catecholamines
  - Increased catecholamine metabolites (metanephrines) and free catecholamines.
  - Plasma metanephrines if available (most sensitive).
  - Cut-off values will depend on assay used.
- CT abdomen
  - If negative, whole body CT and meta-iodo-benzoguanidine (MIBG) scintigraphy, Octreoscan, or MRI.

Treatment

- Surgical removal of tumour (curative) with careful pre- and post-operative ICU monitoring.
- Adequate pre-operative preparation
  - α-blockade for BP control: doxazosin or phenoxybenzamine (these are the most frequently used alpha blockers) (10-21 d pre-operative), IV phentolamine (perioperative, if required).
  - β-blockade for HR control once α blocked for a few days.
  - Metyrosine (catecholamine synthesis inhibitor) + alpha blocker.
  - Volume restoration with vigorous salt-loading and fluids.
- Rescreen urine 1-3 mo post-operatively.
- All patients are currently offered genetic testing - probability of germline disease increases with young age, multifocal disease, in the setting of paraganglioma.
Disorders of Multiple Endocrine Glands

Multiple Endocrine Neoplasia

- neoplastic syndromes involving multiple endocrine glands
- tumours of neuroectodermal origin
- autosomal dominant inheritance with variable penetrance
- genetic screening for RET proto-oncogene on chromosome 10 has long-term benefit in MEN 2
  - early cure and prevention of medullary thyroid cancer

MEN 2 (chromosome 10)

1. Men 2a (Gipple’s Syndrome) | Thyroid (>90%) | Physical signs are variable and often subtle |
| | Medullary thyroid cancer (MTC) | Neck mass or thyroid nodule; non-tender, anterior lymph nodes |
| | Adrenal medulla (40-50%) | HTN, palpitations, headache, sweating |
| | Pheochromocytoma (40-50%) | |
| | Parathyroid (10-20%) | Symptoms of hypercalcemia |
| 1° parathyroid hyperplasia | Scaly skin rash |
| Skin | Cutaneous lichen amyloidosis |

2. Familial Medullary Thyroid Ca (a variant of 2a) | Thyroid | MTC without other clinical manifestations of MEN 2a or 2b |
| | MTC (>95%) | |

3. 2b | Thyroid | MTC, most common component, more aggressive and earlier onset than MEN 2a |
| | MTC | HTN, palpitations, headache, sweating |
| | Adrenal medulla | Chronic constipation; megacolon |
| | Pheochromocytoma (>50%) | |
| Neurons | Mucosal neuroma, intestinal ganglioneuromas (100%) | Marfanoid habitus (no aortic abnormalities) |
| Skin | Cutaneous lichen amyloidosis |

Investigations

- MEN 1
  - laboratory
    - offer genetic testing to patients with a clinical diagnosis of MEN 1
      - if a mutation is identified, screen family members who are at risk
    - gastrinoma: elevated serum gastrin level (>200 ng/mL) after IV injection of secretin
    - insulinoma: hypoglycemia with insulin and C-peptide levels that are inappropriately high for the level of glucose
    - glucagonoma: elevated glucagon levels
    - pituitary tumours: assess GH, IGF-1, and prolactin levels (for over-production), TSH, free T4, 8 AM cortisol, LH, FSH, bioavailable testosterone or estradiol (for underproduction due to mass effect of tumour)
    - hyperparathyroidism: serum Ca++ and albumin, PTH levels; bone density scan (DEXA)
  - imaging
    - MRI for pituitary tumours, CT or MRI for gastrinoma, CT, MRI, or endoscopic ultrasound for insulinoma
Calcium Homeostasis

- MEN 2
  - laboratory
    - genetic screening for RET mutations in all index patients
      - if a mutation is identified, screen family members who are at risk
    - calcitonin levels (MTC); urine catecholamines and metanephrines (pheochromocytoma); serum Ca²⁺, and PTH levels (hyperparathyroidism)
    - pentagastrin ± calcium stimulation test if calcitonin level is within reference range
    - FNA for thyroid nodules cytology
  - imaging
    - CT or MRI of adrenal glands to localize pheochromocytoma
    - Metastatic disease generally picked up with cross-sectional imaging

Treatment

- MEN 1
  - medical
    - proton pump inhibitor (PPI) for acid hypersecretion in gastrinoma
    - cabergoline or other dopamine agonists to suppress prolactin secretion
    - somatostatin analogue for control of symptoms of some of the GI neuroendocrine tumours such as glucagonoma
  - surgery for hyperparathyroidism, insulinoma, glucagonoma, functioning pituitary tumours (except for prolactinomas where dopamine agonists are used, or nonfunctioning pituitary tumours associated with mass effect)
    - trans-sphenoidal approach is generally preferred for pituitary tumours
  - MEN 2
    - surgery for MEN 2a associated manifestations may require pre-operative medical therapy
      - prostaglandin inhibitors to alleviate diarrhea associated with thyroid cancer
      - α-blocker for at least 10-21 d for pheochromocytoma pre-operatively
    - hydration, IV bisphosphonates or denosumab for severe hypercalcemia

- normal total serum Ca²⁺: 2.2-2.6 mmol/L
- ionic/free Ca²⁺ levels: 1.15-1.31 mmol/L
- serum Ca²⁺ is 40% protein bound (mostly albumin), 50% ionized, and 10% complexed with PO₄³⁻ and citrate
- regulated mainly by two factors: parathyroid hormone (PTH) and vitamin D, whose actions are on three main organs: GI tract, bone, and kidney

Hypercalcemia

Definition
- total corrected serum Ca\(^{2+}\) > 2.6 mmol/L OR ionized Ca\(^{2+}\) > 1.35 mmol/L

Figure 17. Differential diagnosis of hypercalcemia

Primary Hyperparathyroidism is the most common cause of hypercalcemia in healthy outpatients. Most commonly related to a solitary adenoma or less commonly multiple gland hyperplasia. Surgical excision acts as definitive treatment and is recommended for patients who are symptomatic. For mild asymptomatic disease, medical surveillance may be appropriate with annual serum calcium, creatinine, and bone mineral density (BMD).

For asymptomatic patients, surgery is recommended for those who meet ≥1 of the following criteria:
- Serum calcium concentration more than 0.25 mmol/L (1.0 mg/dL) above the upper limit of normal
- Creatinine clearance < 60 mL/min
- BMD T-score <-2.5 at hip, spine, or distal radius, and/or previous fragility fracture
- Age < 50 yr

Total Ca\(^{2+}\) does not reflect ionized Ca\(^{2+}\) in the following circumstances:
- abnormal albumin levels
- critical illness
- chronic hepatic failure/renal failure
In circumstances where the albumin is low, you should perform an ionized calcium assessment.
If ionized calcium is not available, total calcium can be corrected for albumin using this approximation:

\[
\text{Corrected Ca}^{2+} (\text{mmol/L}) = \text{measured Ca}^{2+} + 0.02(40 - \text{albumin})
\]
- for every decrease in albumin by 10, increase in Ca\(^{2+}\) by 0.2
Approach to Hypercalcemia
1. Is the patient hypercalcemic?
2. Is the PTH high/normal or low?
3. If PTH is low, is phosphate high/normal or low?
4. If phosphate is high/normal, is the level of vitamin D metabolites high or low?

Clinical Features
- symptoms depend on the absolute Ca²⁺ value and the rate of its rise (may be asymptomatic)

** Hypercalcemic crisis (usually >4 mmol/L or 16 mg/dL): primary symptoms include oliguria/anuria and mental status changes including somnolence and eventually coma - this is a medical emergency and should be treated immediately!

Treatment
- treatment depends on the Ca²⁺ level and the symptoms
- treat the underlying cause of the hypercalcemia
- treat acute, symptomatic hypercalcemia aggressively
- mild asymptomatic hypercalcemia: monitor, avoid: thiazide, volume depletion, high Ca²⁺ diet, lithium, bed rest

Signs and Symptoms of Acute Hypocalcemia
- Paresthesias: perioral, hands, and feet
- Chvostek’s sign: percussion of the facial nerve just anterior to the external auditory meatus elicits ipsilateral spasm of the orbicularis oculi or orbicularis oris muscles
- Troussseau’s sign: inflation of a blood pressure cuff above systolic pressure for 3 min elicits carpal spasm and paresthesia

Watch Out for:
- Volume depletion via diuresis
- Arrhythmias

Hypermagnesemia can impair PTH secretion and action
Approach to Hypocalcemia
1. Is the patient hypocalcemic?
2. Is the PTH high or low?
3. If PTH is high, is phosphate low or normal?
4. Is the Mg\(^{2+}\) level low?

Approach to Treatment
- correct underlying disorder
- treat concurrent hypomagnesemia
- mild and symptomatic (ionized Ca\(^{2+}\) >0.8 mmol/L)
  - calcium supplementation - 1500-2000 mg of elemental calcium/d
  - calcitriol 0.25 µg/d (especially in renal failure or hypoparathyroidism)
- note: this dose is typically higher in hypoparathyroidism
- acute or symptomatic hypocalcemia (ionized Ca\(^{2+}\) <0.7 mmol/L)
  - immediate treatment required
  - IV calcium gluconate 1-2 g over 10-20 min followed by slow infusion
  - if underlying cause is hypoparathyroidism, the goal is to raise Ca\(^{2+}\) to low normal range (2.0-2.1 mmol/L) to prevent symptoms but allow maximum stimulation of PTH secretion
- if PTH recovery not expected, requires long-term therapy with calcitriol and calcium
- start oral calcium and calcitriol concurrently with IV calcium infusion
- do not correct hypocalcemia if asymptomatic and suspected to be transient

Figure 18. Etiology and clinical approach to hypocalcemia
Metabolic Bone Disease

• see 2010 Clinical Practice Guidelines for the Diagnosis and Management of Osteoporosis for details

Osteoporosis

Definition
• a condition characterized by decreased bone mass and microarchitectural deterioration with a consequent increase in bone fragility and susceptibility to fracture
• BMD is measured at hip and lumbar spine, BMD T-score ≤−2.5 is indicative of osteoporosis
• osteopenia (low bone mass): BMD with T-score between −1.0 and −2.5

Etiology and Pathophysiology

Secondary Osteoporosis
• gastrointestinal diseases
  - gastrectomy
  - malabsorption (e.g. celiac disease)
  - chronic liver disease
• bone marrow disorders
  - multiple myeloma
  - lymphoma
  - leukemia
• endocrinopathies
  - Cushing’s syndrome
  - hyperparathyroidism
  - hyperthyroidism
  - premature menopause
  - DM
  - hypogonadism
• malignancy
  - secondary to chemotherapy
  - myeloma
• drugs
  - corticosteroid therapy
  - phenytoin
  - chronic hepatic therapy
  - androgen deprivation therapy
  - aromatase inhibitors
  - rheumatologic disorders
    - rheumatoid arthritis
    - SLE
  - ankylosing spondylitis
  - renal disease
  - poor nutrition
  - immobilization
• COPD (due to disease, tobacco, and glucocorticoid use)

Clinical Features
• commonly asymptomatic
• height loss due to collapsed vertebral
• fractures: most commonly in hip, vertebrae, humerus, and wrist
  - fragility fractures: fracture with fall from standing height or less
  - Dowager’s hump: collapse fracture of vertebral bodies in mid-dorsal region
  - x-ray: vertebral compression fractures (described as wedge fractures, require a minimum of 20% height loss), “cod/fishing” sign (weakening of subchondral plates and expansion of intervertebral discs)
• pain, especially backache, associated with fractures

Approach to Osteoporosis
1. assess risk factors for osteoporosis on history and physical
2. decide if patient requires BMD testing with dual-energy x-ray absorptiometry (DEXA): men and women ≥65 yr (or younger if presence of risk factors, see Table 33, E44)
3. initial investigations
  - all patients with osteoporosis: calcium corrected for albumin, CBC, creatinine, ALP, TSH
  - also consider serum and urine protein electrophoresis if vertebral fractures, celiac workup, and 24 h urinary Ca-excretion to rule out additional secondary causes
  - 25-OH-Vitamin D level should only be measured after 3-4 mo of adequate supplementation and should not be repeated if an optimal level ≥75 nmol/L is achieved
  - lateral thoracic and lumbar x-ray if clinical evidence of vertebral fracture (or in individuals at moderate risk of fracture to help decide if they require medical therapy)
4. assess 10-yr fracture risk by combining BMD result and risk factors
  1) WHO Fracture Risk Assessment Tool (FRAX)
  2) Canadian Association of Radiologists and Osteoporosis Canada Risk Assessment Tool (CAROC)
  * approach to management guided by 10-yr risk stratification into low, medium, high risk
5. for all patients being assessed for osteoporosis, encourage appropriate lifestyle changes (see Table 34, E44)
Table 33. Osteoporosis Risk Stratification

<table>
<thead>
<tr>

<th>High Risk</th>
</tr>
</thead>
<tbody>
<tr>
<td>10 yr fracture risk &lt;10%</td>
<td>Unlikely to benefit from pharmacotherapy; encourage lifestyle changes</td>
<td>Start pharmacotherapy</td>
</tr>
<tr>
<td>Reassess risk in 5 yr</td>
<td>Discuss patient preference for management and consider additional risk factors</td>
<td>Repeat BMD and reassess risk every 1-3 yr initially</td>
</tr>
<tr>
<td>10 yr fracture risk 10-20%</td>
<td>Factors that warrant consideration for pharmacological therapy: Additional vertebral fracture(s) identified on vertebral fracture assessment (VFA) or lateral spine x-ray Previous wrist fracture in individuals &gt;65 or with T-score &lt; -2.5 Lumbar spine T-score much lower than femoral neck T-score Rapid bone loss Men receiving androgen-deprivation therapy for prostate cancer Women receiving aromatase-inhibitor therapy for breast cancer Long-term or repeated systemic glucocorticoid use (oral or parenteral) that does not meet the conventional criteria for recent prolonged systemic glucocorticoid use Recurrent falls (defined as falling 2 or more times in the past 12 mo) Other disorders strongly associated with osteoporosis</td>
<td>10 yr fracture risk &gt;20%; OR Prior fragility fracture of hip or spine; OR More than one fragility fracture</td>
</tr>
</tbody>
</table>

**Table 34. Treatment of Osteoporosis in Women and Men**

**Treatment for Both Men and Women**

- **Lifestyle**
  - Diet: Elemental calcium 1000-1200 mg/d; Vit D 1000 IU/d
  - Exercise: 3x30 min weight-bearing exercises, balance exercise, and aerobic exercise/wk
  - Cessation of smoking, reduce caffeine intake
  - [Stop/avoid osteoporosis-inducing medications](#)

- **Drug Therapy**

  - **Bisphosphonate:** inhibitors of osteoclast binding
    - 1st line in prevention of hip, nonvertebral, and vertebral # (Grade A): alendronate (PO), risedronate (PO), zoledronic acid (IV)
  - **RANKL Inhibitors**
    - Denosumab: 1st line in prevention of hip, nonvertebral, vertebral # (Grade A)
    - Denosumab should not be abruptly stopped/administration delayed. Increased risk of vertebral fractures due to increased bone turnover on discontinuation
  - **Parathyroid Hormone (teriparatide)**
    - 18-24 mo duration, followed by long-term anti-resorptive therapy with bisphosphonate or RANKL inhibitor followed by long-term anti-resorptive therapy with bisphosphonate or RANKL inhibitor

**Treatment Specific to Post-Menopausal Women**

- **SERM (selective estrogen-receptor modulator): agonistic effect on bone but antagonistic effect on uterus and breast**
  -Raloxifene: 1st line in prevention of vertebral # (Grade A)
  -+ve: prevents osteoporotic # (Grade A to B evidence), improves lipid profile, decreased breast cancer risk
  --ve: increased risk of DVT/PE, stroke mortality, hot flashes, leg cramps

- **HRT: combined estrogen + progesterone**
  - [see Gynecology, GY34](#)
  - 1st line in prevention of hip, nonvertebral, and vertebral # (Grade A)
  - For most women, risks > benefits
  - Combined estrogen/progesterin prevents hip, vertebral, total #
  - Increased risks of breast cancer, cardiovascular events, and DVT/PE
Osteomalacia and Rickets

- Osteopenia with disordered calcification leading to a higher proportion of osteoid (unmineralized) tissue prior to epiphyseal closure: rickets (in childhood), osteomalacia (in adulthood)

**Etiology and Pathophysiology**

**Vitamin D Deficiency**
- Deficient uptake or absorption
  - Nutritional deficiency
  - Malabsorption: post-gastrectomy, small bowel disease (e.g., Celiac sprue), pancreatic insufficiency
- Defective 25-hydroxylation
  - Liver disease
  - Anticonvulsant therapy (phenytoin, carbamazepine, phenobarbital)
- Loss of vitamin D binding protein
  - Nephrotic syndrome
- Defective 1-α-25 hydroxylation
  - Hypoparathyroidism
- Renal failure
- Pathophysiology: leads to secondary hyperparathyroidism and hypophosphatemia

**Mineralization Defect**
- Abnormal matrix
  - Osteogenesis imperfecta
- Enzyme deficiency
  - Hypophosphatasia (inadequate ALP bioactivity)
- Presence of calcification inhibitors
  - Aluminum, high dose fluoride, anticonvulsants

**Table 35. Clinical Features of Rickets and Osteomalacia**

</tbody>
</table>

| Conditions associated with abnormal matrix formation | Normal | Normal | Normal |

- radiologic findings
  - pseudofractures, fissures, narrow radiolucent lines – thought to be healed stress fractures or the result of erosion by arterial pulsation
  - loss of distinctness of vertebral body trabeculae; concavity of the vertebral bodies
  - changes due to secondary hyperparathyroidism: subperiosteal resorption of the phalanges, bone cysts, resorption of the distal ends of long bones
  - others: bowing of tibia, coxa profunda hip deformity
  - bone biopsy: usually not necessary but considered the gold standard for diagnosis

Treatment

- definitive treatment depends on the underlying cause
- vitamin D supplementation
- PO$_4^{3-}$ supplements if low serum PO$_4^{3-}$, Ca$^{2+}$ supplements for isolated calcium deficiency
- bicarbonate if chronic metabolic acidosis

Renal Osteodystrophy

- changes to mineral metabolism and bone structure secondary to chronic kidney disease
- represents a mixture of four types of bone disease:
  - osteomalacia: low bone turnover combined with increased unmineralized bone (osteoid)
  - adynamic bone disease: low bone turnover due to excessive suppression of parathyroid gland
  - osteitis fibrosa cystica: increased bone turnover due to secondary hyperparathyroidism
  - mixed uremic osteodystrophy: both high and low bone turnover, characterized by marrow fibrosis and increased osteoids
- metastatic calcification secondary to hyperphosphatemia may occur

Pathophysiology

- metabolic bone disease secondary to chronic renal failure
- combination of hyperphosphatemia (inhibits 1,25(OH)2-Vit D synthesis) and loss of renal mass (reduced 1-α-hydroxylase)

Clinical Features

- soft tissue calcifications, necrotic skin lesions if vessels involved
- osteodystrophy, generalized bone pain and fractures
- pruritus
- neuromuscular irritability and tetany may occur (with low serum calcium)
- radiologic features of osteitis fibrosa cystica, osteomalacia, osteosclerosis, osteoporosis

Investigations

- serum Ca$^{2+}$ corrected for albumin, PO$_4^{3-}$, PTH, ALP, ± imaging (x-ray, BMD), ± bone biopsy

Treatment

- prevention
- maintenance of normal serum Ca$^{2+}$ and PO$_4^{3-}$ by restricting PO$_4^{3-}$ intake to 1 g OD
- Ca$^{2+}$ supplements; PO$_4^{3-}$ binding agents (calcium carbonate, aluminum hydroxide)
- vitamin D with close monitoring to avoid hypercalcaemia and metastatic calcification

Paget’s Disease of Bone

Definition

- a metabolic disease characterized by excessive bone destruction and repair

Epidemiology

- 3% of the population, 10% of population >80 yr old
- consider Paget’s disease of bone in older adults with ↑ ALP but normal GGT
Etiology and Pathophysiology
• postulated to be related to a slowly progressing viral infection of osteoclasts, possibly paramyxovirus
• strong familial incidence
• initiated by increased osteoclastic activity leading to increased bone resorption; osteoblastic activity increases in response to produce new bone that is structurally abnormal and fragile

Differential Diagnosis
• osteogenic sarcoma
• multiple myeloma
• fibrous dysplasia
• osteitis fibrosa cystica
• metastases

Clinical Features
• usually asymptomatic (routine x-ray finding or elevated serum ALP)
• 3 characteristic findings: osteolytic lesions, cortical thickening, pseudofractures (small fissures which develop in the convex surface of long bone)
• most commonly affects: skull, thoracolumbar spine, pelvis, and long bones of lower extremities
• severe bone pain (e.g. pelvis, femur, tibia)
• skeletal deformities: bowed tibias, kyphosis, frequent fractures
• increased risk of osteosarcoma and giant cell tumours

Investigations
• laboratory
  • high serum ALP, normal or high Ca²⁺, normal PO₄³⁻
  • elevated c-telopeptide (CTX) (bone resorption marker, breakdown product of collagen in the blood)
• imaging
  • confirmation on x-ray required for diagnosis
    • denser bone with cortical thickening
    • characteristic findings: osteolytic lesions, cortical thickening & pseudofractures
    • Paget disease-related signs include: Tam o’Shanter sign (appearance of advanced Paget disease of the skull – overall enlargement of cranium, skull falling over the facial bones), blade of grass sign (lucent leading edge in a long bone seen in lytic phase of Paget’s), osteoporosis circumscripta (radiolucent regions of the skull), jigsaw pattern bone or mosaic pattern bone (thickened, disorganized trabeculae lead to areas of sclerosis), picture frame vertebra (cortex of vertebral body is thickened), cotton wool appearance of bone (results from thickened, disorganized trabeculae that lead to areas of sclerosis), banana fracture (horizontal pathological fracture seen in bones deformed by Paget’s), ivory vertebra sign (diffuse and homogenous increase in opacity of a vertebral body)
  • Burned-out Paget’s disease: when the disease has been there for a long time
    • bone scan to evaluate the extent of disease and identify asymptomatic sites

Complications
• local
  • fractures; osteoarthritis
  • cranial nerve compression and palsies (e.g. deafness), spinal cord compression
  • osteosarcoma/sarcomatous change in 1-3%
    • indicated by marked bone pain, new lytic lesions and suddenly increased ALP
• systemic
  • hypercalcemia and nephrolithiasis
  • high output CHF due to increased vascularity

Treatment
• goals: decrease pain, decrease rate of remodelling
• weight-bearing exercise
• adequate calcium and vitamin D intake to prevent development of secondary hyperparathyroidism
• treat medically if symptomatic or asymptomatic with ALP >3x normal or planned surgery
  • bisphosphonates, e.g. zoledronic acid 5 mg IV per yr (preferred) OR alendronate 40 mg PO OD x 6 mo OR risedronate 30 mg PO OD x 3 mo
  • calcitonin 50-100 U/d SC if unable to tolerate bisphosphonate
• surgery for fractures, deformity, degenerative changes
Androgen Regulation

- Testosterone (from Leydig cells) primarily involved in negative feedback on LH and GnRH, whereas inhibin (from Sertoli cells) suppresses FSH secretion.

Tests of Testicular Function

- Testicular size (lower limit = 4 cm x 2.5 cm in adult). Can use orchidometer to measure testicular volume (12–25 ml = adult size)
- LH, FSH, total, bioavailable, and/or free testosterone
- Semen analysis
  - Semen volume, sperm concentration, morphology, and motility are the most commonly used parameters
- Testicular biopsy
  - Indicated with normal FSH and azoospermia/oligospermia

Hypogonadism and Infertility

- See Urology, U36
- Deficiency in gametogenesis or testosterone production

Etiology

- Causes include primary (testicular failure), secondary (hypothalamic-pituitary failure), and idiopathic.

Diagnosis of Testosterone Deficiency Syndrome (i.e., adult onset primary hypogonadism)

- Requires clinical manifestations of testosterone deficiency (see sidebar) AND documented testosterone levels below the laboratory reference range (confirmed on x2 separate analyses, test needs to be done at 8–9 AM when testosterone is usually at its peak)
- Rule out secondary causes

Table 37. Classification and Features of Hypogonadism

Diagnosis

- Testicular size and consistency (soft/firm)
- Sperm count
- LH, FSH, total, and/or bioavailable testosterone
- HCG stimulation (mainly used in pediatrics)
- Karyotype

- Testicular size and consistency (soft/firm)
- Sperm count
- LH, FSH, total, and/or bioavailable testosterone
- Prolactin levels (and pituitary panel - T4/AM cortisol)
- Fe, Transferin
- MRI of hypothalamic-pituitary region
E49  Endocrinology  Male Reproductive Endocrinology

Treatment
- goal: testosterone replacement (improve libido, muscle mass, strength, body hair growth, bone mass)
  - IM injection, transdermal testosterone patch/gel, oral
  - side effects: acne, fluid retention, erythrocytosis, sleep apnea, benign prostatic hypertrophy,
    uncertain effects on cardiac events/mortality in older men
  - contraindicated in men with prostate or breast cancer, a palpable prostate nodule, PSA>4 ng/mL,
    elevated hematocrit, untreated severe OSA, severe LUTS, uncontrolled CHF, MI or stroke in last 6
    mo, or thrombophilia
  - not suggested in men >65, in men with T2DM with low testosterone concentrations, or in men
    planning fertility in the near term
  - testosterone therapy only to treat symptoms of hypogonadism, often results in decreased
    spermatogenesis by further suppression of hypothalamic-pituitary-gonadal axis
- goal: fertility
  - treat underlying cause
  - GnRH agonist if hypothalamic dysfunction with intact pituitary, administered SC in pulsatile
    fashion using an external pump
  - hCG and recombinant follicular stimulating hormone (rFSH) in cases of either hypothalamic or
    pituitary lesions
  - dopamine agonist (e.g. bromocriptine, cabergoline) if prolactinoma
  - testicular sperm extraction (TESE) or microscopic sperm extraction (MICROTESE) – only if
    testicular tissues are not functioning

Other Causes of Male Infertility
- hereditary disorders: Kartagener syndrome (primary ciliary dyskinesia), cystic fibrosis (absence of
  the vas deferens)
- anatomy: hypospadias, retrograde ejaculation
- obstruction: vasal occlusion, vasal aplasia, vasectomy, seminal vesicle disease
- sexual dysfunction: erectile dysfunction, premature ejaculation, infrequent coitus
- surgery: TURP, radical prostatectomy, orchietomy

DEFECTS IN ANDROGEN ACTION

Etiology
- complete androgen insensitivity (CAIS)
- partial androgen insensitivity (PAIS)
- 5-α-reductase deficiency
- mixed gonadal dysgenesis
- defects in testosterone synthesis
- infertile male syndrome
- undervirilized fertile male syndrome

Clinical Features
- depends on age of onset

Table 38. Effects of Testosterone Deficiency

</tbody>
</table>

Adapted from: UpToDate, 2010; Cicci’s Essentials of Medicine

Treatment
- gender assignment in the newborn
- hormone replacement or supplementation
- psychological support
- gonadectomy for cryptorchidism (due to increased risk for testicular cancer)
- reduction mammoplasty for gynecomastia

Erectile Dysfunction
- see Urology, U33
Gynecomastia

Definition
- true gynecomastia refers to benign proliferation of the glandular component of the male breast, resulting in the formation of a concentric, rubbery, firm mass extending from the nipple(s)
- pseudogynecomastia or lipomastia refers to enlargement of soft adipose tissue, especially seen in obese individuals

Etiology

Physiologic
- puberty
- elderly
- neonatal (maternal hormone)

Pathologic
- physiologic gynecomastia – trimodal distribution in neonatal, pubertal and older males
- drugs – spironolactone, cimetidine, ketoconazole, recombinant human GH, hCG, estrogens, antiandrogens, GnRH agonists, 5-alpha reductase inhibitors
- hormone therapy for prostate cancer
- starvation and refeeding
- male hypogonadism
- cirrhosis
- treatment of HIV infection – due to fat tissue as part of lipodystrophy
- herbal products – plant-derived oils as lavender and tea tree oil
- men with history of testicular neoplasms
- CKD
- other rare causes: feminizing adrenal tumours, disorders of sex development, ectopic hCG, familial prepubertal gynecomastia
- hyperthyroidism

Pathophysiology
- hormonal imbalance due to:
  - increased estrogen activity
  - increased production, or increased availability of estrogen precursors for peripheral conversion to estrogen
  - decreased androgen activity
  - decreased androgen production, binding of androgen to sex hormone binding globulin (SHBG), or androgen receptor blockage

History
- recent change in breast characteristics
- pain
- trauma to testicles
- mumps
- alcohol and/or drug use
- FHx
- sexual dysfunction

Physical Exam
- signs of feminization
- breast
  - rule out red flags suggesting breast cancer: unilateral, eccentric, hard or fixed mass, skin dimpling or retraction, and nipple discharge or crust ing
  - gynecomastia occurs concentrically around nipple, is not fixed to underlying tissue
- genito-urinary exam
- stigmata of liver or thyroid disease

Investigations
- laboratory: serum TSH, PRL, LH, FSH, testosterone, estradiol, LFTs, creatinine, hCG (if hCG is elevated, need to locate the primary tumour); however not all investigations are required for every case of gynecomastia
- CXR and CT of chest/abdomen/pelvis (to locate neoplasm)
- testicular U/S (if primary hypogonadism suspected or mass on physical examination)
- MRI of hypothalamic-pituitary region if secondary hypogonadism or pituitary adenoma suspected

Treatment
- initial observation for most men with gynecomastia (after stopping offending medications and treating underlying cause)
- medical
  - correct the underlying disorder, discontinue responsible drug
  - androgens for hypogonadism
  - anti-estrogens: tamoxifen has most evidence for benefit
- surgical
  - longstanding (>12 mo, fibrotic), discomfort, or causing psychological distress
Paraneoplastic Syndrome

- clinical syndromes involving non-metastatic systemic effects that accompany malignant disease
- triggered by antibodies against neoplasm cross-reacting with normal tissue or by production of a physiologically active substance by the neoplasm
- commonly present with cancers of lung, breast, ovaries, or lymphatic system

Investigations
- CBC, electrolytes, creatinine, LFTs, ALP, ESR, CRP, serum/urine electrophoresis
- serum autoantibodies, lumbar puncture
- imaging: skeletal survey, CT, MRI, PET scan
- ± endoscopy

Treatment
- treat underlying tumour: surgery, radiation, chemotherapy
- treat immune-mediated disorder: IVIG, steroids, immunosuppressive drugs, plasmapheresis (reserved for patients with identifiable antibodies in serum)
## Diabetes Medications

day

Four Principles of Family Medicine

1. The family physician is a skilled clinician
   - diagnoses and manages diseases common to the population served
   - recognizes importance of early diagnosis of serious life-threatening illnesses

2. Family medicine is a community-based discipline
   - provides information and access to community services
   - responds/adapts to changing needs and circumstances of the community

3. The family physician is a resource to a defined practice population
   - serves as a health resource
   - advocates for public policy to promote health

4. The patient-physician relationship is central to the role of the family physician
   - commits to the person, not just the disease
   - promotes continuity of patient care

Periodic Health Examination

- Canadian Task Force on Preventive Health Care established in 1976 to develop and disseminate clinical practice guidelines for primary and preventive care
- recommendations are based on systematic analysis of scientific evidence
- periodic preventive health visits are recommended instead of annual physical examinations

Purpose of the Periodic Health Examination

- primary prevention: identify risk factors for common diseases; counsel patients to promote healthy behaviour
- secondary prevention: pre-symptomatic detection of disease to allow early treatment and to prevent disease progression

Classification of Recommendations (GRADE, 2011)

Strength of Recommendation
- strong: confidence that desirable effects outweigh undesirable effects (strong recommendation for an intervention) or that the undesirable effects outweigh desirable effects (strong recommendation against an intervention)
- implies that most individuals will be best served by the recommended course of action
• **conditional:** desirable effects probably outweigh the undesirable effects (conditional recommendation for an intervention) or undesirable effects probably outweigh the desirable effects (conditional recommendation against an intervention)
  • implies that most people would want the recommended course of action but that many would not
  • different choices will be appropriate for different individuals, patients require support in reaching a management decision consistent with his/her values and preferences

**Quality of Evidence**
• high: high level of confidence that true effect lies close to the estimate of the effect
• moderate: true effect likely to be close to the estimate of the effect, but there is a possibility that it is substantially different
• low or very low: true effect may be substantially different from the estimate of the effect

**Table 1. Periodic Health Exam**

---

**Breast Cancer Screening Guidelines**

**2018 Canadian Task Force on Preventive Health Care**
• average-risk women: women age 40-74 with no personal history of breast cancer, history of breast cancer in 1st degree relatives, known mutations of the BRCA1/BRCA2 genes or previous exposures of the chest wall to radiation

---

**Folic Acid Supplementation in Pregnancy (Joint SOGC-Motherisk Clinical Guideline May 2015)**
• To prevent neural tube defects in all women capable of becoming pregnant
• Low risk women (no personal health risks, planned pregnancy): diet of folate-rich foods and a daily oral multivitamin supplement containing 0.4-1.0 mg folic acid for at least 2-3 mo before conception, throughout pregnancy, and 4 to 6 wk postpartum or as long as breast-feeding continues
• High risk women (health risks including epilepsy, insulin-dependent diabetes, BMI >35, family history of NTD, high risk ethnic group): diet of folate-rich foods and daily supplementation with multivitamins with 5 mg folic acid at least 3 mo prior to conception until 12 wk post conception
• From wk 6 post-conception until postpartum period (4-6 wk or as long as breastfeeding continues): 0.4-1.0 mg of folic acid supplementation is sufficient
• Women with additional lifestyle issues (poor compliance with medications, no consistent birth control, taking possible teratogenic substances): higher folic acid dose of 5 mg and counselling about prevention of birth defects

---

**Choosing Wisely Canada**
http://www.choosingwiselycanada.org/
A campaign to help clinicians and patients engage in conversations about unnecessary tests and treatments and make smart and effective choices to ensure high quality care
**Mammography**
- age 40-49: recommend not screening with mammography (conditional recommendation, low-certainty evidence)
- age 50-74: recommend routine screening q2-3yr (conditional recommendation, very low-certainty evidence)
- age 75+: screen if benefits outweigh harm, must take overall health into account

**Magnetic Resonance Imaging and Ultrasound**
- recommend not using MRI, tomosynthesis or ultrasound to screen for breast cancer in women not at increased risk (strong recommendation, no evidence)

**Clinical Breast Examination**
- recommend not performing CBE to screen for breast cancer (conditional recommendation, no evidence)

**Breast Self-Examination**
- recommend against routine breast self-examination to screen for breast cancer (conditional recommendation, low-certainty evidence)
- for more information on benign breast lesions and breast cancer, see General Surgery, GS60

**Lung Cancer Screening Guidelines**
2016 Canadian Task Force on Preventive Health Care
- apply to adults aged 18 and older who are not suspected of having lung cancer
- recommend low dose CT scan for annual screening in adults aged 55-74 with at least a 30 pack-yr smoking history who currently smoke or quit less than 15 yr ago, up to three consecutive times
- chest x-ray is not recommended to screen for lung cancer, with or without sputum cytology

**Colorectal Cancer Screening Guidelines**
2016 Canadian Task Force on Preventive Health Care
- apply to average risk individuals (asymptomatic, no family history of UC, polyps, or CRC)
- average risk testing should begin at age 50, but assessment for risk factors should begin earlier to identify high-risk individuals 50-59 (conditional recommendation, moderate quality evidence), 60-74 (strong recommendation, moderate quality evidence)
- recommend screening with FOBT (either high sensitivity FOBT or FIT) q2yr OR flexible sigmoidoscopy q10yr
- colonoscopy not recommended as a screening test
- screening is not recommended after age 75, but it may be assessed on an individual basis for ages 76-85
- for more information on colorectal neoplasms, see General Surgery, GS38

---

**Figure 1. Approach to higher risk screening**

AAPC = attenuated adenomatous polyposis; FAP = familial adenomatous polyposis; HNPCC = hereditary nonpolyposis colorectal cancer; 1st degree relatives: parents, siblings, children; 2nd degree relatives: grandparents, aunts, uncles; 3rd degree relatives: great grandparents or cousins. Figure printed with permission from Can J Gastroenterol 2004;18:93-99. Also see: Colorectal Screening for Cancer Prevention in Asymptomatic Patients, March 2013. Available from http://www.bcguidelines.ca/pdf/colorectal_screening.pdf
Cervical Cancer Screening Guidelines

- either conventional Papanicolaou (Pap) smear or liquid based cytology testing
- endocervical and exocervical cell sampling (aim is to sample the transitional zone)
- best identifies squamous cell abnormalities, less reliable for glandular abnormalities
  - false positives 5-10%, false negatives 10-40% (for single test)
  - false negative rate 50% for existing cervical cancer
- cervical cancer screening guidelines differ by provincial jurisdiction (see The Society of Obstetricians and Gynaecologists of Canada guidelines)

2013 Canadian Task Force for Preventive Care Guidelines

- recommend screening all women age ≥25 q3yr who are or have ever been sexually active (includes intercourse or digital/oral activity with partner of either sex); age 25-29 (conditional recommendation; moderate quality evidence), age 30-69 (strong recommendation; high quality evidence)
- can recommend discontinuing screening in women age ≥70: if 3 normal tests in a row and no abnormal tests in last 10 yr, (conditional recommendation; low quality evidence)

Ontario guidelines

- screen all women age ≥21 who are or have ever been sexually active
  - if cytology is normal, can screen every 3 yr
  - women age ≥70: if 3 successive negative Pap tests in last 10 yr, can discontinue screening
  - women who are not sexually active by age 21 should delay cervical cancer screening until sexually active
- pregnant women and women who have sex with women should follow the routine cervical screening regimen
- women who have had a hysterectomy
  - total: discontinue screening if hysterectomy was for benign disease and no history of cervical dysplasia or HPV infection, continue to swab vaginal vault if history of uterine malignancy/dysplasia
  - subtotal: continue screening according to guidelines
- exceptions to guidelines
  - immunocompromised (transplant, steroids, diethylstilbestrol exposure, HIV)
  - previously unscreened patients
- for more information on cervical cancer (see Gynecology, GY43)

Prostate Cancer Screening Guidelines

2014 Canadian Task Force for Preventative Care Guidelines

- recommend NOT using prostate specific antigen for prostate cancer screening in any age group (age <55: strong recommendation; low quality evidence, age 55-69: conditional recommendation; moderate quality evidence, age >70: strong recommendation; low quality evidence
Health Promotion and Counselling

- health promotion is the most effective preventive strategy
- there are several effective ways to promote healthy behavioural change, such as discussions appropriate to a patient's present stage of change
- for more information, see www.motivationalinterviewing.org

Motivational Strategies for Behavioural Change

<table>
<thead>
<tr>
<th>Patient's Stage of Change</th>
<th>Physician's Aim</th>
<th>Physician's Plan</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pre-Contemplation</td>
<td>Encourage patient to consider the possibility of change</td>
<td>Raise issue in a sensitive manner</td>
</tr>
<tr>
<td></td>
<td>Assess readiness for change</td>
<td>Offer (not impose) a neutral exchange of information to avoid resistance</td>
</tr>
<tr>
<td></td>
<td>Increase patient’s awareness of the problem and its risks</td>
<td></td>
</tr>
<tr>
<td>Contemplation</td>
<td>Understand patient’s ambivalence and encourage change</td>
<td>Offer opportunity to discuss pros and cons of change using reflective listening</td>
</tr>
<tr>
<td></td>
<td>Build confidence and gain commitment to change</td>
<td></td>
</tr>
<tr>
<td>Preparation</td>
<td>Explore options and choose course most appropriate to patient</td>
<td>Offer realistic options for change and opportunity to discuss inevitable difficulties</td>
</tr>
<tr>
<td></td>
<td>Identify high-risk situations and develop strategies to prevent relapse</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Continue to strengthen confidence and commitment</td>
<td></td>
</tr>
<tr>
<td>Action</td>
<td>Help patients design rewards for success</td>
<td>Offer positive reinforcement and explore ways of coping with obstacles</td>
</tr>
<tr>
<td></td>
<td>Develop strategies to prevent relapse</td>
<td>Encourage self-rewards to positively reinforce change</td>
</tr>
<tr>
<td></td>
<td>Support and reinforce convictions towards long-term change</td>
<td></td>

Nutrition

General Population
- Canada’s Food Guide is appropriate for individuals age ≥2
- counsel on variety, portion size, and plate layout
- vitamins and minerals: see “Functions and Food Sources of Some Common Vitamins” and “Functions and Food Sources of Some Common Minerals” — available from https://www.dietitians.ca/
- Guideline 1: Nutritious foods are the foundation for healthy eating, vegetables, fruits, whole grains, and proteins should be consumed regularly, consume plant based more often. Foods with mostly unsaturated fat should be replaced with those that contain mostly saturated fat. Water should be beverage of choice
- Guideline 2: Processed or prepared foods and beverages that contribute to excess sodium, free sugars, or saturated fat undermine healthy eating, should not be consumed regularly
- Guideline 3: Food skills are needed to navigate the complex food environment and support healthy eating. Cooking and food preparation using nutritious foods should be promoted. Food labels should be promoted as a tool to make informed choices

Energy Content of Food
- Carbohydrates 4 kcal/g
- Protein 4 kcal/g
- Fat 9 kcal/g
- Ethanol 7 kcal/g

Calculating Total Daily Energy Expenditure (TDEE)
- Roughly 25 kcal/kg/d
- Varies by age, weight, sex, and activity level
- Average 2000-2100 kcal/d for women, 2700-2900 kcal/d for men

Handy Serving Size Comparisons
- 3 oz meat, fish, poultry → palm of hand
- 1 cup dairy (milk/yogurt) → size of fist
- Bread/grains → one slice, palm of hand
- ½ cup rice/pasta → one hand cupped
- 1 cup of fruit/vegetables → two cupped hands
- 1 oz cheese → full length of thumb
- 1 tsp oil/butter → tip of thumb
- Nuts/chips/snacks → palm covered

Obesity

2015 Canadian Task Force on Preventive Health Care Recommendations

- body mass index (BMI) = weight (kg)/height (m)^2 = weight (lbs)/height (in)^2 x 703; poor predictor of obesity
- waist circumference (WC) = flexible tape placed on horizontal plane at iliac crest; normal depends on ethnic background
- increased WC for BMI 25-35 increases the risk of cardiovascular disease and type 2 diabetes

Table 4. Classification of Weight by BMI, Waist Circumference, and Associated Disease Risks in Adults

* Disease risk for type 2 diabetes, hypertension, and CVD.

Epidemiology

- 20.2% of Canadians aged 18 and older (excluding pregnant women) were obese in 2014 (StatsCan, 2014)
- obesity remains higher in Aboriginal populations compared with non-Aboriginal populations with 25.7% of Aboriginal adults (excluding First Nations on-reserve) estimated to be obese (CCHS 2007/2008)
- close to a third of 5-17 yr were identified as overweight or obese (2009 to 2011 CHMS)
- overweight and obesity rates in children are directly proportional to screen time (see Exercise, FM10)
Screening Recommendations
- CANRISK or FINRISC scores can be used to assess the risk for type 2 DM in overweight and obese patients
- recommends measuring height and weight and then calculating BMI at appropriate primary care visits

Management

Behavioural/Lifestyle
- weight loss of >5% is clinically significant for reducing many cardiovascular risk factors (e.g. elevated blood pressure, glucose, and lipids)
- efficacious behavioural interventions: >12 mo duration, include diet, exercise, lifestyle components, and group and individual sessions
- structured behavioural and lifestyle interventions should be offered or arranged for overweight individuals BMI >25
- strong recommendation for those with increased risk of Type 2 DM
- BMI >35 and risk factors or BMI >40 are candidates for bariatric surgery failing behavioural modification

Pharmacologic
- recommends against pharmacologic intervention to manage patients who are overweight and obese, although some patients may prefer medications and be good candidates for pharmacologic treatment
- high benefit of behavioural modification alone, NNH (number needed to harm) 10 (mostly GI side effects) for pharmacotherapy

Figure 4. 2006 Canadian clinical practice guidelines on the management and prevention of obesity in adults and children
Adapted from: CMAJ 2007;176:S1-S13
**Dyslipidemia**

- **see Endocrinology, E3**
- **definition:** abnormal elevation of plasma cholesterol or triglyceride levels

### Assessment

**RISK ASSESSMENT, STRATIFICATION AND TREATMENT CONSIDERATION**

- **Calculate risk** (unless statin-indicated condition) using the Framingham Risk Score (FRS) or Cardiovascular Life Expectancy Model (CLEM)
- **Repeat screening every 5 years for FRS <5% or every year for FRS ≥5%**

**No Pharmacology**

- **Primary Prevention Conditions**
  - **Low Risk**
    - FRS <10%
  - **Intermediate Risk**
    - FRS 10-19% and LDL-C ≥3.5 mmol/L, or Non-HDL-C ≥4.3 mmol/L or alternative method

**Statin-Indicated Conditions**

- **Clinical atherosclerosis**
  - Abdominal aortic aneurysm
  - Most diabetes including: Type 1 DM
- **LDL-C ≥5 mmol/L**
  - Genetic dyslipidemia

#### Discuss Behavioural Modifications

1. Smoking cessation
2. Diet: adopt a health dietary pattern
3. Exercise: for adults 150 min/wk of moderate-vigorous aerobic

#### Initiate Statin Treatment: Treat to Target Approach

**YES**

- Target achieved on maximally tolerated dose?

**NO**

- Discuss add-on therapy with patient (evaluate reduction in CVD risk vs. additional cost & side effects)

**ADD-ON**

- **Monitor Response to statin Rx**
- **Health behaviour**

- **Health Promotion and Counselling**
- **1st line: Ezetimibe (BAS as alternative)**
- **2nd line: PCSK9 inhibitors (add-on to other drugs)**
- **1st line: Ezetimibe or BAS (FRS ≥20% or ≥20 year duration)**

#### Safety of Statins: An Update

- **Trials have shown that statin therapy slightly increases the incidence of diabetes; however, the absolute risk is small. Relative to the reduction in coronary events, the clinical significance is not great enough to recommend against their use.**

### Risk Factors for Screening for Dyslipidemia

- **First Nations or South Asian ancestry**
- **Current cigarette smoking**
- **Diabetes**
- **Arterial Hypertension**
- **Family history of premature CVD**
- **Family history of hyperlipidemia**
- **Erectile dysfunction**
- **Chronic kidney disease**
- **Inflammatory disease (lupus, rheumatoid arthritis, psoriatic arthritis, IBD)**
- **HIV infection**
- **Chronic obstructive pulmonary disease**
- **Clinical evidence of atherosclerosis or abdominal aneurysm**
- **Clinical manifestation of hyperlipidemia**
- **Obesity (BMI>27)**

### Non-fasting Lipids vs. Fasting Lipids

- **Non-fasting (TC and non-HDL cholesterol) can be used for Framingham Risk Assessment and hold same prognostic value as fasting lipids**
- **In fasted vs. non-fasted samples, non-HDL and TC varies by 2%, LDL-C by 10% and TG by 20%**
- **In non-fasting (TC and non-HDL cholesterol) can be used for Framingham Risk Assessment and hold same prognostic value as fasting lipids**
- **Non-fasting (TC and non-HDL cholesterol) can be used for Framingham Risk Assessment and hold same prognostic value as fasting lipids**

### To calculate Framingham Risk Score, go to

Management
- intensity and type of treatment is guided by “risk category” assigned (see Figure 5)
  1. Health behaviours (can decrease LDL-C by up to 10%)
    - smoking cessation: probably the most important for preventing CAD
    - dietary modification: reduce saturated fat, red meat, refined sugar, alcohol; consume nuts, fruits/vegetables, poultry, fish
    - physical activity: at least 150 min of moderate to vigorous intensity aerobic exercise per wk, in bouts of 10 min or more to reduce CVD risk (see Table 5)
    - employ consistent lifestyle modifications for at least 3 mo before considering drug therapy; high risk patients should start treatment immediately with concurrent health behaviour interventions
  2. Pharmacologic therapy (can decrease LDL-C by up to 40%)
    - for a comparison of dyslipidemia medications, see Endocrinology, E3
    - 1st line monotherapy: statins (HMG-CoA reductase inhibitors)
      - risks: myopathy and hepatotoxicity
      - if severe side effects: ezetimibe (cholesterol absorption inhibitor) can be used for 19% reduction in LDL-C
      - post-acute coronary syndrome, cholesterol absorption inhibitors (e.g. ezetimibe) in addition to simvastatin reduced mortality, attained lipid targets <1.8, and improved outcomes in high risk individuals
    - lower evidence for other agents: bile acid sequestrants, nicotinic acid, fibrates, psyllium
    - monitoring
    - ALT, CK, creatinine at baseline then 6 wk later for signs of transaminitis or myositis; tolerate rise in CK
    - drug therapy (lowers risk for pancreatitis, not CAD)
      - lower evidence for other agents: bile acid sequestrants, nicotinic acid, fibrates, psyllium
    - monitoring
    - ALT, CK, creatinine at baseline then 6 wk later for signs of transaminitis or myositis; tolerate rise in CK
    - drug therapy (lowers risk for pancreatitis, not CAD)
      - nicotinic acid
      - fibrates

Isolated Hypertriglyceridemia
- does not increase cardiovascular risk
- normal HDL-C and TC, elevated TG
- mild ≥2.2 mmol/L (≥200 mg/dL); marked ≥5.6 mmol/L (≥500 mg/dL)
- principal therapy is lifestyle modification
  - weight loss, exercise, avoidance of smoking and alcohol, effective blood glucose control in diabetics, increased omega-3 fatty acid intake
  - severe hypertriglyceridemia (typically >10 mmol/L) is associated with an increased risk of acute pancreatitis
- drug therapy (lowers risk for pancreatitis, not CAD)
  - nicotinic acid
  - fibrates

Exercise

Table 5. Canadian 24-Hour Movement Guidelines (2017 CSEP Guidelines)

<table>
<thead>
<tr>
<th>Age Category</th>
<th>Physical Activity Guidelines</th>
<th>Example Activities</th>
<th>Sleep/Sit Guidelines</th>
</tr>
</thead>
<tbody>
<tr>
<td>Infant (&lt;1)</td>
<td>Active several times daily</td>
<td>Tummy time for at least 30 min/d</td>
<td>Sleep: 14-17 h/d of good quality sleep including naps</td>
</tr>
<tr>
<td></td>
<td>Tummy time for at least 30 min/d</td>
<td>Interactive floor-based play including tummy time, reaching for toys, crawling</td>
<td>Sit: not restrained (i.e. in a stroller) for more than 1 h, screen time not recommended, engaging in reading/storytelling while sedentary</td>
</tr>
<tr>
<td>Toddler (1-2)</td>
<td>Accumulate 180 min of physical activity at any intensity spread throughout the day including energetic play</td>
<td>Moving around the home Climbing stairs Exploring environment Brisk walking, running, dancing</td>
<td>Sleep: 11-14 h/d of good quality sleep including naps</td>
</tr>
<tr>
<td>Preschool (2-4)</td>
<td>Accumulate &gt;180 min in a variety of activities at any intensity, including at least 60 min of energetic play throughout the day</td>
<td>Moving around the home Climbing stairs Exploring environment Brisk walking, running, dancing</td>
<td>Sit: not restrained (i.e. in a stroller) for more than 1 h, screen time not recommended, engaging in reading/storytelling while sedentary</td>
</tr>
<tr>
<td>Children (5-11) and Youth (12-17)</td>
<td>Moderate to vigorous aerobic and muscle/bone strengthening exercises 60 min/3x/wk Light physical activity for several hours per day</td>
<td>Moderate: bike riding, playground Vigorous: running, swimming</td>
<td>Sleep: 8-11 h/d (5-13 yr), 8-10 h/d (16-17 yr)</td>
</tr>
<tr>
<td>Adults (18-64)</td>
<td>Accumulate 150 min of moderate to vigorous intensity aerobic physical activity per wk, in bouts of 10 min or more It is beneficial to add muscle and bone strengthening activities using major muscle groups, at least 2 d/wk</td>
<td>Moderate: brisk walking, bike riding Vigorous: jogging, cross country skiing</td>
<td>Sit: no more than 2 h/d of recreational screen time, limit sitting for extended periods</td>
</tr>
<tr>
<td>Older Adults (≥65)</td>
<td>Same as Adults above</td>
<td>Those with poor mobility should perform physical activities to enhance balance and prevent falls</td>
<td>No specific guidelines</td>
</tr>
</tbody>
</table>
Epidemiology
- 25% of the population exercises regularly, 50% occasionally, 25% are sedentary

Management
- assess current level of fitness, motivation, and access to exercise
- encourage warm up and cool down periods to allow transition between rest and activity and to avoid injuries
- exercise with caution for patients with CAD, DM (risk of hypoglycemia), exercise-induced asthma
- patients with known CAD should have cardiac assessment prior to commencing exercise
- benefits of exercise
  - reduces risk of premature death, heart disease, stroke, HTN, certain types of cancer, type 2 DM, osteoporosis, and overweight/obesity
  - leads to improved fitness, strength, and mental health (morale and self-esteem)

Smoking Cessation
Epidemiology
- smoking is the single most preventable cause of premature illness and death
- 70% of smokers see a physician each year
- 2012 Canadian Tobacco Use Monitoring Survey (CTUMS) on population age ≥15
  - 16% are current smokers (lowest since 1965)
  - highest prevalence in age group 20–24 (20%)
  - 11% of youth age 15–19 smoke (decreased from 25% in 2000): more males smoke than females; number of cigarettes consumed per day also decreasing

Management
- general approach
  - identify tobacco users; elicit smoking habits, previous quit attempts, and results
  - 2012 CAN-ADAPTT Guidelines
    - tobacco use status should be updated for all patients regularly
    - health care providers should clearly advise patients to quit
    - health care providers should also monitor the patient's mental health status/other addictions while quitting smoking
  - medication dosage should be monitored and adjusted as necessary
    - every smoker should be offered treatment
  - combining counselling and smoking cessation medication is more effective than either alone
    - educate patient to watch for withdrawal symptoms
    - low mood, insomnia, irritability, anxiety, difficulty concentrating, restlessness, decreased heart rate, increased appetite
      - ≥4 counselling sessions >10 min each with 6–12 mo follow-up yields better results
      - 14% abstinent with counselling vs. 10% without counselling
    - approach depends on patient's stage of change (see Motivational Strategies for Behavioural Change, FM6)
  - willing to quit
    - provision of social support, community resources (self-help, group, helpline, web-based strategies)
    - pregnant patients: counselling is recommended as first line treatment
      - nicotine replacement therapy (NRT) should be made available to pregnant women who are unable to quit using non-pharmacologic methods
      - intermittent NRT use (lozenges, gum) is preferred over continuous dosing of the patch
      - no strong evidence that either major positive or negative outcomes were associated with gestational use of bupropion or varenicline; consider using only if benefits outweigh risks and consult Motherisk Helpline
    - pharmacologic therapy
      1. Nicotine Replacement Therapy
        - 19.7% abstinent at 12 mo with NRT vs. 11.5% for placebo
      - no difference in achieving abstinence for different forms of NRT
      - reduces cravings and withdrawal symptoms without other harmful substances that are contained in cigarettes
        - use with caution: immediately post-MI, worsening angina, arrhythmia
        - advise no smoking while using NRT
    2. Antidepressants (mechanism of action appears to be independent of antidepressant effect)
      - bupropion SR (Zyban™)
        - 21% abstinent at 12 mo vs. 8% for placebo
      - similar effectiveness of NRT vs. bupropion
    3. Varenicline (Champix™)
      - partial nicotinic receptor agonist (to reduce cravings) and partial competitive nicotinic receptor antagonist (to reduce the response to smoked nicotine)
      - more effective than bupropion (23% abstinent from 9–32 wk with varenicline vs. 16% with bupropion vs. 9% with placebo)
      - significant side effects may lower patient compliance

Conclusion
: The antidepressants bupropion and nortriptyline can aid smoking cessation and have a similar efficacy to NRT. Bupropion is less effective than varenicline. Neither SSRIs (e.g. fluoxetine) nor MAOIs aid smoking cessation.

Physician Advice for Smoking Cessation
Cochrane Database Syst Rev 2013;5:CD000165
Purpose: To assess the efficacy and safety of antidepressants for long-term smoking cessation.
Methods: Systematic review of RCTs comparing antidepressant medications to placebo or alternative medications for smoking cessation. Studies comparing different doses, use of pharmacotherapy for relapse prevention or re-initiation of smoking cessation, or those targeting reduction in cigarette consumption by smokers, were also considered eligible. Eligible studies were required to have a minimum of 8 mo follow-up.
Results: 90 trials were included. Antidepressants had a significantly increased long-term cessation including bupropion alone (RR: 1.33, 95% CI 1.19–1.49) and nortriptyline alone (RR: 1.36, 95% CI 1.21–1.55), which appeared equally effective to each other and to nicotine replacement therapy (NRT). No significant additional long-term benefits found with adding bupropion (RR: 1.04, 95% CI 0.94–1.15) or nortriptyline (RR: 1.15, 95% CI 0.96–1.38). Significant lower quit rates (RR: 0.66, 95% CI 0.58–0.76) and increased adverse events close to statistical significance (RR: 1.08, 95% CI 1.00–1.17) were found with bupropion compared to nortriptyline. The evidence showed significant effectiveness for selective serotonin reuptake inhibitors (SSRIs) (RR: 1.31, 95% CI 1.19–1.44) in addition to NRT (RR: 1.24, 95% CI 1.14–1.35), whereas monoamine oxidase inhibitors alone (RR: 1.26, 95% CI 1.05–1.51), varenicline (RR: 1.12, 95% CI 1.02–1.23), and St. John’s wort (hypericum RR: 1.08, 95% CI 0.92–1.25) or SAMe-containing supplement (RR: 1.23, 95% CI 1.14–1.32).
Conclusion: The antidepressants bupropion and nortriptyline can aid smoking cessation and have a similar efficacy to NRT. Bupropion is less effective than varenicline. Neither SSRIs (e.g. fluoxetine) nor MAOIs aid smoking cessation.

Assist Patient in Developing Quit Plan
Cochrane Database Syst Rev 2013;5:CD000165
Purpose: To assess the effectiveness of physician advice in promoting smoking cessation, compare minimal physician interventions to maximal interventions, and determine the effect of anti-smoking advice on mortality.
Methods: Systematic review of RCTs of smoking cessation advice from a health care provider. Abstinence was assessed at least 6 mo after advice was provided.
Results: 42 trials with over 31,000 smokers were identified. Most common setting for advice delivery was primary care. A significant increase in quit rates was noted with advice versus no advice (Relative risk RR: 1.39, 95% CI 1.26–1.52). The exception was advice given to patients with no intention to quit where the intervention was considered more effective than usual care (RR: 1.04, 95% CI 0.82–1.32). An additional significant increase in smoking cessation rate was noted in those who viewed the advice as ‘very helpful’ or ‘helpful’ compared to those who did not (RR: 1.29, 95% CI 1.15–1.44). A small benefit with follow-up was found, but this was not statistically significant or clinically relevant (RR: 1.02, 95% CI 1.00–1.04).
Conclusion: Simple advice can increase cessation rates by 1–3%. More intensive advice and providing follow-up support may further increase quit rates.

Physician Advice for Smoking Cessation

</tbody>
</table>

* Buproprion and varenicline may be used in combination with nicotine replacement therapy

- unwilling to quit
  - motivational intervention (5 Rs)
    1. Relevance to patient
      - relevant to patient’s disease status or risk, family or social situation (e.g. having children in the home), health concerns, age, gender
    2. Risks of smoking
      - short-term: SOB, asthma exacerbation, impotence, infertility, pregnancy complications, heartburn, URTI
      - long-term: MI, stroke, COPD, lung CA, other cancers
      - environmental: higher risk in spouse/children for lung CA, SIDS, asthma, respiratory infections
  - Rewards: benefits
    - improved health, save money, food tastes better, good example to children
  - Roadblocks: obstacles
    - fear of withdrawal, weight gain, failure, lack of support
  - Repetition
    - reassure unsuccessful patients that most people try many times before successfully quitting (average number of attempts before success is 7)
  - recent quitter
    - highest relapse rate within 3 mo of quitting
    - minimal practice: congratulate on success, encourage ongoing abstinence, review benefits and problems
    - prescriptive interventions: address problem of weight gain, negative mood, withdrawal, lack of support

Alcohol Use

- see Psychiatry, PS26

Definition
- alcohol use disorder diagnostic categories occur along a continuum

Epidemiology
- 10-15% of patients in family practice are problem drinkers
- 20-50% of hospital admissions, 10% of premature deaths, 30% of suicides, and 50% of fatal traffic accidents in Canada are alcohol-related
- more likely to miss diagnosis in women, elderly, and patients with high socioeconomic status
Common Presenting Problems

Abdominal Pain

- see Gastroenterology, G4, General Surgery, GS4, and Emergency Medicine, ER59

Epidemiology

- 20% of individuals have experienced abdominal pain within the last 6-12 mo
- 90% resolve in 2-3 wk
- only 10% are referred to specialists, of those <10% admitted to hospital

Etiology

- most common diagnosis in family medicine at 28% is “nonspecific abdominal pain,” which has no identifiable cause and is usually self-limited
- GI disorders (e.g. PUD, pancreatitis, IBD, appendicitis, gastroenteritis, IBS, diverticular disease, biliary tract disease)
- urinary tract disorders (e.g. UTI, renal calculi)
- gynecological disorders (e.g. PID, ectopic pregnancy, endometriosis)
- cardiovascular disorders (e.g. CAD, AAA, ischemic bowel)
- other: DKA, porphyria, hypercalcemia, medications (e.g. NSAIDs), alcohol, toxic ingestion, foreign body, psychogenic
Common Presenting Problems

Pathophysiology
- type of pain
  - somatic pain: sharp, localized pain
  - visceral pain: dull, generalized pain
- location of pain
  - epigastric (foregut): distal esophagus, stomach, proximal duodenum, biliary tree, pancreas, liver
  - RUQ: biliary, hepatic, colonic, pulmonary, renal
  - LUQ: cardiac, gastric, pancreatic, renal, vascular
  - periumbilical (midgut): distal duodenum to proximal 2/3 of transverse colon
  - hypogastrium (hindgut): distal 1/3 of transverse colon to rectosigmoid region
  - RLQ: colonic, appendicular, gynecologic, renal
  - LLQ: colonic, gynecologic, renal
  - any location: aneurysm, dissection, ischemia, zoster, muscle strain, hernia, bowel obstruction, peritonitis, porphyria, DKA

Investigations
- guided by findings on history and physical
- possible blood work: CBC, electrolytes, BUN, Cr, amylase, lipase, AST, ALT, ALP, bilirubin, glucose, INR/PTT, toxicology screen, β-hCG
- imaging
  - CXR (for free air under the diaphragm) in setting of perforation in surgical abdomen
  - abdominal x-ray, KUB (consider: gas pattern, free air, kidney stones, constipation)
  - ultrasound (renal stones, gallbladder disease, gynecological problems, liver disease, pancreatitis, diverticular disease, appendicitis)
  - CT scan (AAA, appendicitis), non-contrast helical CT-Scan (first choice for renal stones)
- other tests
  - urinalysis
  - endoscopy (for peptic ulcers, gastritis, tumours, etc.)
  - H. pylori testing (urea breath test, serology, biopsy)

Allergic Rhinitis
- see Otolaryngology, OT23

Definition
- inflammation of the nasal mucosa that is triggered by an allergic reaction
- classification
  - seasonal
    - symptoms during a specific time of the year
    - common allergens: trees, grass and weed pollens, airborne moulds
  - perennial
    - symptoms throughout the year with variation in severity
    - common allergens: dust mites, animal dander, moulds
- persistent allergic rhinitis may lead to chronic rhinosinusitis

Epidemiology
- affects approximately 40% of children and 20-30% of adults
- prevalence has increased in developed countries, particularly in the past two decades
- associated with asthma, eczema, sinusitis, and otitis media

Etiology
- increased IgE levels to certain allergens → excessive degranulation of mast cells → release of inflammatory mediators (e.g. histamine) and cytokines → local inflammatory reaction

Assessment
- identify allergens
- take an environmental/occupational history
- ask about related conditions (e.g. atopic dermatitis, asthma, sinusitis, and family history)

Management
- conservative
  - minimize exposure to allergens
    - most important aspect of management, often sufficient (may take months)
  - maintain hygiene, saline nasal rinses
- pharmacologic agents
  - oral antihistamines – first line therapy for mild symptoms
    - e.g. cetirizine (Reactine®), fexofenadine (Allegra®), loratadine (Claritin®)
  - intranasal corticosteroids for moderate/severe or persistent symptoms (>1 mo of consistent use to see results)
  - intranasal decongestants (use must be limited to <5 d to avoid rhinitis medicamentosa)

Abdominal Pain Red Flags
- Severe pain
- Signs of shock
- Peritoneal signs
- Abdominal distention
- Pain out of proportion to clinical findings
- New onset pain, change in pain, or altered bowel habit in elderly
- Weight loss
- Blood per rectum/melena
- Anemia
- Supraclavicular nodes
- Family history of serious bowel disease

In patients >50, keep a high index of suspicion for AAA – its presentation may mimic renal colic or diverticulitis

Differential Diagnosis
- Acute viral infection
- Vasomotor rhinitis
- Deviated septum
- Nasal polyps
- Acute/chronic sinusitis
- Drug-induced rhinitis

Rhinitis Medicamentosa
Rebound nasal congestion. Occurs with prolonged use (>5-7 d) of vasoconstrictive intranasal medications. Patient may become dependent, requiring more frequent dosing to achieve the same decongestant effect
• allergy skin testing
  ■ for patients with chronic rhinitis whose symptoms are not controlled by conservative and pharmacological therapy
  ■ may identify allergens to include in immunotherapy treatment
• immunotherapy (allergy shots)
  ■ reserved for severe cases unresponsive to pharmacologic agents
  ■ consists of periodic (usually weekly) subcutaneous injections of custom prepared solutions of one or more antigens to which the patient is allergic

**Amenorrhea**

- see Gynecology, GY7

**Anxiety**

- see Psychiatry, PS20

**Epidemiology**

- 25-30% of patients in primary care settings have psychiatric disorders
- many are undiagnosed or untreated; hence the need for good screening
- high rate of coexistence of anxiety disorders and depression

**Screening**

- screening tools such as the Generalized Anxiety Disorder 7-item (GAD-7) tool
- screening questions
  ■ Do you tend to be an anxious or nervous person?
  ■ Have you felt unusually worried about things recently?
  ■ Has this worrying affected your life? How?

**Assessment**

- associated symptoms
- risk factors: past history of anxiety, stressful life event, trauma, social isolation, female, comorbid psychiatric diagnosis (e.g. depression), family history of anxiety or depression
- assess substance abuse, suicidal ideation/self-harm
- to differentiate anxiety disorders, consider symptoms and their duration
- use the GAD-7 tool to assess and monitor levels of anxiety

**Figure 7. Differentiating anxiety disorders**

Management
- patient education: emphasize prevalence, good recovery rate of anxiety conditions
- lifestyle advice: exercise, decrease caffeine and alcohol intake
- psychological: CBT, including exposure therapy, relaxation techniques, and mindfulness strategies
- pharmacotherapy: see Psychiatry, PS43
- provide self-help materials, connect with community resources (e.g. support groups), and provide support to family and caregivers

Asthma/COPD

- see Respirology, R7

Definition
- asthma
  - chronic, reversible airway inflammation characterized by periodic attacks of wheezing, SOB, chest tightness, and coughing
  - airways are hyper-responsive to triggers/antigens leading to acute obstructive symptoms by bronchoconstriction, mucous plugs, and increased inflammation
  - cannot be diagnosed at first presentation; is called reactive airway disease until recurrent presentations
  - PFTs can be done starting at age 6 or when child is able to follow testing instructions
  - peak flow meters are useful in the office and at home for monitoring
- chronic obstructive pulmonary disease (COPD)
  - group of chronic, progressive, non-reversible lung diseases characterized by limited airflow with variable degrees of air sac enlargement and lung tissue destruction
  - emphysema and chronic bronchitis are the most common forms

Table 8. Differentiating COPD from Asthma

<tr>
<td>Step 3: SABA prn + LAAC + low-dose combined ICS/LABA; consider inhaled vs. oral steroids</td>
<td>Step 1: Low-dose ICS</td>
</tr>
<tr>
<td><strong>Severe</strong></td>
<td>Step 2: Medium/high-dose ICS or low-dose ICS plus either LABA, LT modifier, or long-acting theophylline</td>
</tr>
<tr>
<td>Step 4: ± theophylline</td>
<td>Step 3: Medium/high-dose ICS + either LABA, LT modifier, or long-acting theophylline</td>
</tr>
<tr>
<td>Pneumococcal vaccination, annual influenza immunization</td>
<td>Step 4: As above + immunotherapy ± oral glucocorticosteroids + pneumococcal vaccination, annual influenza immunization</td>
</tr>
</tbody>
</table>

ICS = inhaled corticosteroids; LAAC = long-acting anticholinergic; LABA = long-acting β-agonist; LT modifier = leukotriene modifier; SABA = short-acting β-agonist

More About Inhalers
- Aerosols (puffers=MDI, MDI + spacer)
  - MDIs should be used with spacers to:
    - Increase efficiency of use
    - Improve amount inhaled
    - Reduce side effects

More Common: congestive heart disease, COPD
- More rarely: chronic obstructive pulmonary disease, cardiovascular disease, diabetes mellitus

When prescribing salbutamol, watch out for signs of hypokalemia: lethargy, irritability, parasthesias, myalgias, weakness, palpitations, N/V, polyuria

Figure 8. Expiratory flow volume curves (obstructive, normal, and restrictive disease)

See Respirology. R7 Adapted from: Weisberger SE. Principles of pulmonary medicine, 5th Ed. With permission from Elsevier. ©2008
Benign Prostatic Hyperplasia

• see Urology, U7

Definition
• hyperplasia of the stroma and epithelium in the periurethral transition zone

History and Physical
• include current/past health, surgeries, trauma, current medications including OTC
• specific urinary symptoms
• physical exam must include DRE for size, symmetry, nodularity, and texture of prostate (prostate is symmetrically enlarged, smooth, and rubbery in BPH)

Investigations
• urinalysis to exclude UTI and for microscopic hematuria (common sign)
• serum PSA: protein produced by prostatic tissue
  - values
    • <4.0 ng/mL: normal, but must take into account patient’s age and velocity of PSA increase
    • 4-10 ng/mL: consider measuring free/total PSA
    • >10 ng/mL: high likelihood of prostate pathology
• PSA testing is inappropriate in men with a life expectancy less than 10 yr or patients with prostatitis, UTI
• increased PSA in a younger man is more often due to cancer than other causes
• abnormal DRE or PSA should trigger further assessment
• discuss test with men at increased risk of prostate cancer (FHx, African ancestry) or who are concerned about development of prostate cancer
• decision to test PSA in an asymptomatic man should involve discussion about the risks and possible benefits
• other tests
  • Cr, BUN, post-void residual volume by ultrasound, urodynamic studies, renal ultrasound, patient voiding diary
• tests NOT recommended as part of routine initial evaluation include:
  • cystoscopy, cytology, prostate ultrasound or biopsy, IVP, urodynamic studies

Table 9. Symptoms and Complications of BPH

Management
• referral to urologist if moderate/severe symptoms
• conservative: for patients with mild symptoms or moderate/severe symptoms considered by the patient to be non-bothersome
  • fluid restriction (avoid alcohol and caffeine)
  • avoidance/monitoring of certain medications (e.g. antihistamines, diuretics, antidepressants, decongestants)
  •pelvic floor/Kegel exercises
  • bladder retraining (scheduled voiding)
• pharmacological: for moderate/severe symptoms
  • α-receptor antagonists (e.g. terazosin [Hytrin®], doxazosin [Cardura®], tamsulosin [Flomax®], alfuzosin [Xatal®])
    • relax smooth muscle around the prostate and bladder neck
  • 5α reductase inhibitors (e.g. finasteride [Proscar®])
    • only for patients with demonstrated prostatic enlargement due to BPH
    • inhibit the enzyme responsible for conversion of testosterone to dihydrotestosterone (DHT) thus reducing growth of prostate
  • phytotherapy (e.g. saw palmetto berry extract, Pygeum africanum)
    • more studies are required before it can be recommended as standard therapy (currently considered safe)
• surgical
  • TURP (transurethral resection of the prostate), TUIP (transurethral incision of the prostate, for prostate <30 g)
  • absolute indications: failed medical therapy, intractable urinary retention, benign prostatic obstruction leading to renal insufficiency
  • complications: impotence, incontinence, ejaculatory difficulties (retrograde ejaculation), decreased libido

Self-Management Asthma and COPD
Education and Written Action Plan
• Education is a key component in management of asthma and COPD
• Guided self-management combining education, regular medical review, self-assessment, and written action plan have been shown to reduce hospitalizations, ER visits, and missed days at work or school.
• Sample action plans available online: http://www.respiratoryguidelines.ca

Differential Diagnosis
• Prostate cancer
• Urethral obstruction
• Bladder neck obstruction
• Neurogenic bladder
• Overactive bladder
• Cystitis
• Prostatitis
Common Presenting Problems

Bronchitis (Acute)

Definition
- acute infection of the tracheobronchial tree causing inflammation leading to bronchial edema and mucus formation

Epidemiology
- 5th most common diagnosis in family medicine, and most common is URTI

Etiology
- 80% viral: rhinovirus, coronavirus, adenovirus, influenza, parainfluenza, and respiratory syncytial virus (RSV)
- 20% bacterial: M. pneumoniae, C. pneumoniae, S. pneumoniae

Investigations
- acute bronchitis is typically a clinical diagnosis
- sputum culture/Gram stain is not useful
- CXR if suspect pneumonia (cough >3 wk, abnormal vital signs, localized chest findings) or CHF
- PFT with methacholine challenge if suspect asthma

Management
- primary prevention: frequent hand washing, smoking cessation, avoid irritant exposure
- symptomatic relief: rest, fluids (3-4 L/d when febrile), humidity, analgesics, and antitussives as required
- bronchodilators may offer improvement of symptoms (e.g. salbutamol)
- current literature does not support routine antibiotic treatment for the management of acute bronchitis because it is most likely to be caused by a viral infection
  - antibiotics may be useful if elderly, comorbidities, suspected pneumonia, or if the patient is toxic (see Antimicrobial Quick Reference, FM51)
- antibiotics in children show no benefit

Chest Pain

- see Cardiology and Cardiac Surgery, C4 and Emergency Medicine, ER21

Differential Diagnosis

Table 10. Differential Diagnosis of Chest Pain

</tbody>
</table>

Common Presenting Problems

Investigations
- ECG, CXR, and others if indicated (cardiac enzymes, d-dimers, liver function tests, etc.)
- refer to ED if suspect serious etiology (e.g. aortic dissection, MI)

Management of Common Causes of Chest Pain
- angina/ischemic heart disease
  - nitroglycerin (NTG): wait 5 min between sprays and if no effect after 3 sprays, send to ED
  - myocardial infarction
    - ASA (160-325 mg, chewed stat), clopidogrel (Plavix®), LMWH (enoxaparin), morphine, oxygen, NTG
    - ± reperfusion therapy with fibrinolytics (e.g. tissue plasminogen activator (tPA), reteplase (rPA), tenecteplase (TNK), or streptokinase (SK)) if within 12 h (ideally <30 min) or percutaneous intervention (cath lab) if <90 min
    - start β-blocker (e.g. metoprolol starting dose 25 mg PO q6h or bid, titrating to HR goal of 55-60 bpm)
  - endocarditis: antibiotic choice is based on whether patient has a native or prosthetic heart valve as well as culture and sensitivity results
  - GERD: antacids, H2-blockers, PPIs, patient education
  - costochondritis: NSAIDs

Common Cold (Acute Rhinitis)

- see Infectious Diseases, Pneumonia and Influenza, ID7

Definition
- viral URTI with inflammation

Epidemiology
- most common diagnosis in family medicine, peaks in winter months
- incidence: adults = 2-4/yr, children = 6-10/yr
- organisms
  - mainly rhinoviruses (30-35% of all colds)
  - others: coronavirus, adenovirus, RSV, influenza, parainfluenza, coxsackie virus
- incubation: 1-5 d
- transmission: person-person contact via secretions on skin/objects and by aerosol droplets

Risk Factors
- psychological stress, excessive fatigue, allergic nasopharyngeal disorders, smoking, sick contacts

Clinical Features
- symptoms
  - local: nasal congestion, clear to mucopurulent secretions, sneezing, sore throat, conjunctivitis, cough
  - general: malaise, headache, myalgias, mild fever
- signs
  - erythematous nasal/oropharyngeal mucosa, enlarged lymph nodes
  - normal chest exam
- complications
  - secondary bacterial infection: otitis media, sinusitis, bronchitis, pneumonia
  - asthma/COPD exacerbation

Differential Diagnosis
- allergic rhinitis, pharyngitis, influenza, laryngitis, croup, sinusitis, bacterial infections

Management
- patient education
  - symptoms peak at 1-3 d and usually subside within 1 wk
  - cough may persist for days to weeks after other symptoms disappear
  - no antibiotics indicated because of viral etiology
  - secondary bacterial infection can present within 3-10 d after onset of cold symptoms
- prevention
  - frequent hand washing, avoidance of hand to mucous membrane contact, use of surface disinfectant
  - yearly influenza vaccination
- symptomatic relief
  - rest, hydration, gargling warm salt water, steam, nasal irrigation (spray/pot)
  - analgesics and antipyretics: acetaminophen, ASA (not in children because risk of Reye's syndrome), ibuprofen
  - cough suppression: dextromethorphan or codeine if necessary (children <6 yr of age should not use any cough/cold medications)
  - decongestants, antihistamines
  - patients with reactive airway disease will require increased use of bronchodilators and inhaled steroids

see Infectious Diseases, Pneumonia and Influenza, ID7

Definition
- viral URTI with inflammation

Epidemiology
- most common diagnosis in family medicine, peaks in winter months
- incidence: adults = 2-4/yr, children = 6-10/yr
- organisms
  - mainly rhinoviruses (30-35% of all colds)
  - others: coronavirus, adenovirus, RSV, influenza, parainfluenza, coxsackie virus
- incubation: 1-5 d
- transmission: person-person contact via secretions on skin/objects and by aerosol droplets

- allergic rhinitis, pharyngitis, influenza, laryngitis, croup, sinusitis, bacterial infections

Management
- patient education
  - symptoms peak at 1-3 d and usually subside within 1 wk
  - cough may persist for days to weeks after other symptoms disappear
  - no antibiotics indicated because of viral etiology
  - secondary bacterial infection can present within 3-10 d after onset of cold symptoms
- prevention
  - frequent hand washing, avoidance of hand to mucous membrane contact, use of surface disinfectant
  - yearly influenza vaccination
- symptomatic relief
  - rest, hydration, gargling warm salt water, steam, nasal irrigation (spray/pot)
  - analgesics and antipyretics: acetaminophen, ASA (not in children because risk of Reye's syndrome), ibuprofen
  - cough suppression: dextromethorphan or codeine if necessary (children <6 yr of age should not use any cough/cold medications)
  - decongestants, antihistamines
  - patients with reactive airway disease will require increased use of bronchodilators and inhaled steroids
Common Presenting Problems

Concussion/Mild Traumatic Brain Injury

- see Neurosurgery, NS31 and Emergency Medicine, ER8
- a useful tool for the assessment of individuals and athletes with concussion is the Sport Concussion Assessment Tool, 5th edition (SCAT5), Br J Sports Med 2017:0:1-8

Contraception

- see Gynecology, GY15

EMERGENCY CONTRACEPTION

- hormonal EC (Yuzpe® or Plan B®, usually 2 doses taken 12 h apart) or post-coital copper IUD insertion
- hormonal EC is effective if taken within 72 h of unprotected intercourse (reduces chance of pregnancy by 75-85%), most effective if taken within 24 h, does not affect an established pregnancy
- copper IUDs inserted within 5 d of unprotected intercourse are significantly more effective than hormonal EC (reduces chance of pregnancy by ~99%)
- pregnancy test should be performed if no menstrual bleeding within 21 d of either treatment
- advance provision of hormonal EC increases the use of EC without decreasing the use of regular contraception
- pharmacists across Canada can dispense Plan B® OTC

Cough

History and Physical

- duration (chronic - 8 wk), onset, frequency, quality (dry vs. productive), sputum characteristics, provoking/relieving factors, recent changes
- associated symptoms: fever, dyspnea, hemoptysis, wheezing, chest pain, orthopnea, PND, rhinitis, reflux, post-nasal drip
- constitutional symptoms: fever, chills, fatigue, night sweats
- risk factors: smoking, occupation, exposure, family history of lung CA or other CA, TB status, recent travel
- medications (e.g. ACEI, β-blockers), allergies
- PMH: lung (asthma, COPD, CF), heart (CHF, MI, arrhythmias), chronic illness, GI (reflux)
- vitals including O2 saturation, respiratory exam, HEENT and precordial exam

Investigations

- guided by findings on history and physical
- consider throat swab, CXR, PFTs, upper GI series, sputum culture test for acid-fast bacilli (if TB is suspected)

Dementia (Major Neurocognitive Disorder)

- see Psychiatry, PS23

Epidemiology

- 15% of Canadians ≥65 yr are living with dementia; risk for dementia doubles every 5 yr after age 65
- prevalence of depression in dementia is 20-60%; major depression decreases as dementia severity increases; vascular and mixed dementias have a higher prevalence of depression
- leading types of dementia: Alzheimer’s (40-50%), Mixed (20-25%), Lewy-Body (5-15%), Vascular (5-10%), Frontotemporal (5-10%)

Investigations

- history, physical exam, MMSE, MOCA (best screening test), Dementia Quick Screen (see sidebar)
- investigations are completed to exclude reversible causes of dementia and should be selected based on the clinical circumstances
- CBC, liver enzymes, TSH, renal function tests, serum electrolytes, serum calcium, serum glucose, vitamin B12, folate, VDRL, HIV, head CT

Management

- treat and prevent reversible causes
- provide orientation cues (e.g. calendars, clocks) and optimize vision and hearing
- family education, counselling, and support (respite programs, group homes)
- pharmacologic therapy: N-methyl-d-aspartate receptor antagonists and cholinesterase inhibitors slow rate of cognitive decline; low-dose neuroleptics and antidepressants can be used to treat behavioural and emotional symptoms
- 20% of patients develop clinical depression, most commonly seen in vascular dementia
Depression

- see Psychiatry, PS12

Etiology
- often presents as non-specific complaints (e.g. sleep disturbance, chronic fatigue, pain)
- depression is a clinical diagnosis and tests are done in order to rule out other causes of symptoms
- 2/3 of patients may not receive appropriate treatment for their depression
- early diagnosis and treatment improve outcomes

Screening Questions
- Canadian Task Force on Preventive Health Care (2013) recommends not routinely screening for depression
- if screening indicated, use the Patient Health Questionnaire (PHQ-2)
  - "Over the past 2 wk, how often have you been bothered by any of the following problems?":
    - little interest or pleasure in doing things
    - feeling down, depressed, or hopeless
  - the PHQ-2 is scored out of 6, with a score of 3 or more considered positive
  - those who screen positive should be evaluated with the PHQ-9 to determine whether they meet criteria for depression
- PHQ-9 tool is useful to diagnose and monitor depression; use Geriatric Depression Scale (GDS) for the geriatric population

Assessment
- risk factors: see Psychiatry, PS12
- personal or family history of depression
- medications and potential substance abuse problems
- high risk for suicide/homicide
  - fill out Form 1 (in Ontario): application by physician to hospitalize a patient against his/her will for psychiatric assessment (up to 72 h)
- functional impairment (e.g. work, relationships)
- at least 5 out of 9 criteria including at least one of anhedonia or depressed mood ≥2 wk for actual diagnosis to be met (see sidebar)
- validated depression rating scales: Beck's Depression Inventory, Zung's self-rating depression scale, Children's Depression Inventory, Geriatric Depression Scale, Personal Health Questionnaire Depression Scale (PHQ-9)
- routine medical workup (physical exam, CBC, TSH, ferritin, folate, B₁₂, electrolytes, urinalysis, glucose, etc.)

Treatment
- goal: full remission of symptoms and return to baseline psychosocial function
- phases of treatment
  - acute phase (8-12 wk): relieve symptoms and improve quality of life
  - maintenance phase (6-12 mo after symptom resolution): prevent relapse/recurrence, must stress importance of continuing medication treatment for full duration to patients
  - treatment options are pharmacotherapy, psychotherapy, or a combination of both
  - combination therapy is synergistic and most effective (refer to EBM in sidebar)
  - treatment of youth (age 10-21)
    - for mild depression, a period of active support and monitoring before initiating treatment is recommended
    - fluoxetine is first line among SSRIs (most evidence)
      - monitor closely for adverse effects such as suicidal ideation and behaviour
    - psychotherapy
      - CBT or interpersonal therapy (IPT) alone can be used for mild depression
      - psychotherapy plus medication is recommended for moderate to severe depression
      - treatment should continue for at least 6 mo
    - ongoing management should include assessment in key domains (school, home, social setting)
    - reassessment and referral is recommended if there is no improvement after 6-8 wk of treatment
    - consider referral for adolescents with moderate/severe depression and coexisting psychosis and/or substance abuse

</tbody>
</table>
**Prognosis**
- up to 40% resolve spontaneously within 6-12 mo
- risks of recurrence: 50% after 1 episode; 70% after 2 episodes; 90% after 3 episodes

**Diabetes Mellitus**
- see Endocrinology, E7
- see Diabetes Mellitus Patient Care Flow Sheet from Canadian Diabetes associated, available from: http://guidelines.diabetes.ca/organizingcare/patientcareflowsheet

**Definition**
- metabolic disorder characterized by the presence of hyperglycemia due to defective insulin secretion, defective insulin action or both

**Classification and Diagnosis**
- see Endocrinology, E7

**Epidemiology**
- major health concern, affecting up to 10% of Canadians
- incidence of type 2 DM is rising due to increasing obesity, sedentary lifestyle, and age of the population
- leading cause of new-onset blindness and renal dysfunction
- Canadian adults with DM are twice as likely to die prematurely compared to persons without DM

**Risk Factors**
- type 1 DM
  - personal or family history of autoimmune disease
- type 2 DM
  - first degree relative with DM
  - age ≥40 yr
  - obesity (especially abdominal), HTN, hyperlipidemia, CAD, vascular disease
  - prior gestational diabetes mellitus, macrosomic baby (>4 kg)
  - PCOS
  - history of IGT or IFG
  - presence of complications associated with DM
  - presence of associated diseases: PCOS, acanthosis nigricans, psychiatric disorders, HIV
  - medications: glucocorticoids, atypical antipsychotics, HAART
- both
  - member of a high risk population (e.g. Aboriginal, Hispanic, Asian, or African descent)

**Screening**
- type 2 DM
  - FBG or HbA1c in everyone ≥40 q3yr, or at high risk using the CANRISK calculator
  - more frequent and/or earlier testing if presence of ≥1 risk factor (see above)
  - gestational diabetes mellitus (see Obstetrics, OB26)
  - all pregnant women between 24-28 wk gestation

**Goals of Therapy**
- see Endocrinology and side bar (SMART Goals)

</table>

### Nonpharmacologic Management
- **diet**
  - can reduce HbA1c by 1-2%
  - moderate weight loss (5%) improves glycemic control and CVD risk factors
  - all diabetics should see a registered dietician for nutrition counselling
  - decrease combined saturated fats and trans-fatty acids to <10% of calories
  - avoid simple sugars, choose low glycemic-index foods, ensure regularity in timing and spacing of meals
- **physical activity and exercise**
  - at least 150 min of aerobic exercise plus 2 sessions of resistance training per wk is recommended
  - encourage 30-45 min of moderate exercise 4-7 d/wk
  - promote cardiovascular fitness: increases insulin sensitivity, lowers BP, and improves lipid profile
  - if using insulin, may require alterations of diet, insulin regimen, injection sites, and self-monitoring

### Self-Monitoring of Blood Glucose
- **type 1 DM**: 3 or more self-tests/d is associated with a 1% reduction in HbA1c
- **type 2 DM**: recommendations vary based on treatment regimen (e.g. insulin dependent requires more frequent monitoring – refer to 2013 Canadian Practice Guidelines)
- if FBG >14 mmol/L, perform ketone testing to rule out DKA
- if bedtime level is <7 mmol/L, have bedtime snack to reduce risk of nocturnal hypoglycemia
**At diagnosis of Type 2 DM**

Start lifestyle intervention (nutrition therapy and physical activity) ± Metformin

- **A1C <8.5%**
  - Symptomatic hyperglycemia with metabolic decompensation

- **A1C ≥8.5%**
  - Start metformin immediately
  - Consider initial combination with another antihyperglycemic agent

**If not at glycemic target (2-3 mo)**

- Start or increase metformin

**If not at glycemic targets**

- Make timely adjustments to attain target A1C within 3-6 mo

---

**Diagram:**

- **A1C** = glycated hemoglobin
- **empa** = empagliflozin
- **lixi** = lixisenatide
- **aio** = alogliptin
- **GI** = gastrointestinal
- **saxa** = saxagliptin
- **sita** = sitagliptin
- **CHF** = congestive heart failure
- **glar** = glargine
- **DPP-4** = dipeptidyl peptidase 4
- **T2D** = type 2 diabetes

---

**Figure 11. Add another agent best suited to the individual by prioritizing patient characteristics:**

**Priority:** Clinical cardiovascular disease

- Degree of hyperglycemia
- Risk of hypoglycemia
- Overweight or obesity
- Cardiovascular disease
- Comorbidities (renal, CHF, hepatic)
- Preferences and access to treatment

**CHOICE OF AGENT**

- Consider relative A1C lowering
- Rare hypoglycemia
- Weight loss or weight neutral
- Effect on cardiovascular outcome
- See therapeutic considerations, consider eGFR
- See cost column; consider access

---

**Figure 12. Add another agent from a different class; add or intensify insulin regimen**

- If not at glycemic targets

---

**Note:** Physicians should refer to the most recent edition of the Compendium of Pharmaceuticals and Specialties Canadian Pharmacists Association, Ottawa, Ontario, Canada for product monographs and for detailed prescribing information.
Common Presenting Problems

Hypoglycemic Agents (Type 2 DM)
- oral
  - biguanide: metformin (Glucophage®)
  - thiazolidinediones: troglitazone (Rezulin®), rosiglitazone (Avandia®)
  - α-glucosidase inhibitor: acarbose (Precose®)
  - nonsulfonylureas: nateglinide (Starlix®), repaglinide (Gluconorm®)
  - sulfonylureas: glyburide (DiaBeta®), glimepiride (Amaryl®), gliclazide (Diamicron®)
  - DPP-4 inhibitor: sitagliptin (Januvia®)
- injectable
  - GLP-1 analogue: liraglutide (Victoza®)

Other Medications Used in DM
- ACEI or ARB in those with any of:
  - clinical macrovascular disease
  - age ≥55
  - age <55 and microvascular complications
- statin in those with any of:
  - clinical macrovascular disease
  - age ≥40
  - age <40 and any of the following:
    - diabetes duration >15 yr and age >30 yr
    - microvascular complications
    - other cardiovascular risk factors
- low dose ASA (81-325 mg)
  - for secondary prevention in people with established CVD (NOT to be used routinely for primary prevention)

Dizziness
- see Otolaryngology, OT6

Epidemiology
- 70% of affected patients see general practitioners initially; 4% are referred to specialists
- frequency is proportional to age; commonest complaint of ambulatory patients age >75

Differential Diagnosis

- **Vertigo** (vestibular)
  - Objective (external world seems to revolve around individual) or subjective (individual revolves in space)
  - Central (15%)
    - Brainstem
    - Cerebellar
  - Peripheral (85%)
    - Inner ear
    - Vestibular nerve
- **Nonvertiginous** (nonvestibular)
  - Feeling “light-headed,” “giddy,” “dazed,” “mentally confused,” or “disoriented”

**Psychogenic**
- Diagnosis of exclusion

**Vascular**
- Basilar migraine
- TIA
- Orthostatic hypotension
- Stokes-Adams syndrome
- Arrhythmia
- CHF
- Aortic stenosis
- Vasovagal episodes
- Metabolic causes

**Ocular**
- Decreased visual acuity

**BPPV** = benign paroxysmal positional vertigo
**TIA** = transient ischemic attack
**VBI** = vertebral basilar insufficiency

Figure 11. Differential diagnosis of dizziness

History
- clarify type of dizziness: vertigo, pre-syncope, disequilibrium, light-headedness
- duration
- exacerbations
  - worse with head movement or eye closure (vestibular)
  - no change with head movement and eye closure (nonvestibular)
  - worse with exercise (cardiac/pulmonary causes)
- associated symptoms
  - neurologic (central)
    - transient diplopia, dysphagia, dysarthria, ataxia (TIA, VBI, migraine)
  - persistent headache, alterations in level of consciousness, sensory and/or motor deficits (CNS)
Common Presenting Problems

- audiologic (peripheral)
  - hearing loss, tinnitus, otalgia, aural fullness
- others
  - N/V (peripheral vestibular disorders)
  - SOB, palpitations (hyperventilation, cardiac problem)
- general medical history
  - HTN, DM, heart disease, fainting spells, cerebrovascular disease, migraines
  - ototoxic drugs: aminoglycosides (gentamicin, streptomycin, tobramycin), erythromycin, ASA, antimalarials
  - hypotension (secondary to diuresis): furosemide, caffeine, alcohol
  - depression/anxiety: can present with light-headedness

Physical Exam/Investigations

- syncopal
  - cardiac (orthostatic changes in vitals), peripheral vascular, and neurologic exams
  - blood work, ECG, 24 h Holter, treadmill stress test, loop ECG, tilt table testing, carotid, vertebral doppler, and EEG
- vertiginous
  - ENT and neurologic exams
  - Dix-Hallpike, consider audiometry and MRI if indicated
- non-syncopal, non-vertiginous
  - assess gait, vision and test for neuropathy
  - cardiac and neurologic exams (cerebellar and cranial nerve function)
  - 3 min hyperventilation trial (patient is coached to hyperventilate until patient becomes dizzy to identify if symptoms are reproducible and confirm that hyperventilation is the etiology of the symptoms), ECG, EEG
  - Romberg test: test for disequilibrium (patient sways towards the side of vestibular dysfunction)

Treatment

- guided by history, physical exam, and investigations
- include education, lifestyle modification, physical maneuvers (e.g. Epley for BPPV), symptomatic management (e.g. antiemetics), pharmacotherapy, and surgery
- refer when significant central disease is suspected, when vertigo of peripheral origin is persistent (lasting >2-4 wk), or if atypical presentation

Domestic Violence/Elder Abuse

INTIMATE PARTNER VIOLENCE

Definition

- includes physical, sexual, emotional, psychological, and financial abuse

Epidemiology

- lifetime prevalence of intimate partner violence against women is between 25-30%
- similar prevalence of intimate partner violence against men, who may be less likely to report due to social stigma
- women who experience abuse have increased rates of injury, death, and health consequences including 50-70% increase in gynecological, central nervous system, and stress-related problems
- occurs in all socioeconomic, educational, and cultural groups with increased incidence in pregnancy, disabled women, bisexuality, and 18-24 age group
- 25-50% chance of child abuse or neglect in families where partner abuse occurs; children exposed to violence in the home are more likely to experience or perpetrate violence later in life (Cycle of Violence)
- physician recognition rates as low as 5%

Presentation

- multiple visits with vague, ill-defined complaints such as: headaches, gastrointestinal symptoms, insomnia, chronic pain, hyperventilation
- may also present with injuries inconsistent with history

Management

- screen ALL patients
  - always have a high index of suspicion
  - asking about abuse is the strongest predictor of disclosure
  - several screening tools (see sidebar) exist to identify victims of partner violence
  - make sure to determine the victim's level of immediate and long-term danger and ask if there are weapons in the house
  - ensure patient safety
  - victim most at risk for homicide when attempting to leave home or following separation
  - safety planning includes ensuring that there is access to an exit in the home, establishing a safe place to go, and having emergency items prepared should the patient need to leave quickly (including money, clothes, keys, medications, and important documents)

Screening Instruments for Domestic Violence

A) Woman Abuse Screening Tool (WAST)-SHORT
1. In general how would you describe your relationship?
   a. A lot of tension
   b. Some tension
   c. No tension
2. Do you and your partner work out arguments with . . .
   a. Great difficulty
   b. Some difficulty
   c. No difficulty
Endorsing either question 1 (“a lot of tension”) or question 2 (“great difficulty”) makes intimate partner violence exposure likely

B) HITS
How often does your partner:
1. Physically hurt you?
2. Insult you?
3. Threaten you with harm?
4. Scream or curse at you?
Each question on HITS to be answered on a 5 point scale ranging from 1 (= never) to 5 (= frequently)
A total score of 10 or greater is significant
provide community resources
- shelter or helpline number with legal advocacy and counselling services
- involve social workers or domestic violence advocates
- appointment for follow-up to assess whether condition is better or worse
- reassure patient that she/he is not to blame and that the assault is a crime
  - goal is to convey the message that "As your doctor, I am concerned for your safety" and "Your partner has a problem that he/she needs help with" and "I want to help you"
- reporting suspected or known child abuse is mandatory
- spousal abuse is a criminal act, but not reportable without the woman's/man's permission
- DOCUMENT all evidence of abuse-related visits for medico-legal purposes

**ELDER ABUSE**
- see [Geriatric Medicine, GM10](#)

---

**Dyspepsia**
- see [Gastroenterology, G10](#)

**Definition and Clinical Features**
- defined as epigastric pain or discomfort
- can be associated with fullness, belching, bloating, heartburn, food intolerance, N/V

**Epidemiology**
- annual incidence 1-2%, prevalence 20-40%

**Etiology**
- common: functional, PUD, GERD, gastritis
- others: cholelithiasis, irritable bowel syndrome, esophageal or gastric cancer, pancreatitis, pancreatic cancer, Zollinger-Ellison syndrome, and abdominal angina

**History**
- symptoms may not be useful in finding cause
- associated with eating, anorexia, N/V, alcohol, NSAID use
- red flags: vomiting, bleeding/anemia, abdominal mass, dysphagia (VBAD)

**Investigations and Management**
- for new onset dyspepsia:
  - <60 yr without high risk features, test for *H. pylori* using the urea breath test or serology
  - ≥60 yr should undergo upper endoscopy to rule out organic pathology
- lifestyle modifications: decrease caffeine and alcohol intake, avoid citrus food, smaller and more frequent meals, avoid supine position right after meals, smoking cessation
- pharmacologic treatment
  - gastric acid suppression: H2 blockers, PPIs; both are effective for PUD and GERD
  - TCAs or prokinetics: e.g. Metoclopramide; effective for functional dyspepsia
  - *H. pylori* eradication
    - do not keep patients on PPI without at least 1 trial off the medication per year (https://choosingwiselycanada.org/perspective/ppi-toolkit/)
    - for non-responders, upper endoscopy should be considered; if endoscopy is negative, defined as functional dyspepsia

---

**Dyspnea**
- see [Respirology, R3](#) and [Emergency Medicine, ER26](#)

**Definition**
- uncomfortable, abnormal awareness of breathing

**History and Physical Exam**
- history
  - cough, sputum, hemoptysis, wheezing, chest pain, palpitations, dizziness, edema, SOB
  - constitutional symptoms
  - history of asthma, allergies, eczema, ASA/NSAID sensitivity, nasal polyps
  - smoking, recreational drugs, medications
  - occupational exposure, environmental exposure (e.g. pets, allergens, smoke)
  - travel and birth place
  - FHx of atopy
  - previous CXR or PFTs
- physical exam: vitals, respiratory, precordial, HEENT, signs of anemia/liver failure/heart failure

---

**H. pylori Eradication**
- Take the following 10 d treatment
  1) PPI 1 tablet 2x/d for 10 d and
  2) Amoxicillin 1 g twice a day for 5 d (day 1-5)
  Followed by
  3) Clarithromycin 500 mg 2x/d (day 6-10) and
  4) Metronidazole 500 mg 2x/d (day 6-10)

**Differential Diagnosis of Dyspepsia**
- Pulmonary
  - COPD
  - Asthma
  - Restrictive lung disease
  - Pneumothorax
  - Congenital lung disease
  - PE
- Cardiac
  - CHF
  - CAD
  - MI (recent or past)
  - Cardiomyopathy
  - Valve dysfunction
  - Pericarditis
  - Arrhythmia
  - Hypertrophy
- Mixed/Other
  - Deconditioning
  - Trauma
  - Pain
  - Neuromuscular
  - Metabolic condition
  - Functional: anxiety, panic attack, hyperventilation
Investigations
- CXR, ECG
- PFTs, ABG acutely if indicated

Management
- ABCs: send to ED if in severe respiratory distress
- depends on cause

**Dysuria**
- see Urology, U10

**Definition**
- the sensation of pain, burning, or discomfort on urination

**Epidemiology**
- in adulthood, more common in women than men
- approximately 25% of women report one episode of acute dysuria per yr
- most common in women age 25-54 and in those who are sexually active
- in men, dysuria becomes more prevalent with increasing age

**Etiology**
- infectious
  - most common cause
  - presents as cystitis, urethritis, pyelonephritis, vaginitis, cervicitis, epididymo-orchitis, or prostatitis
- non-infectious
  - hormonal conditions (hypoestrogenism), obstruction (BPH, urethral strictures), allergic reactions, radiation, drugs/chemicals, foreign bodies, trauma, neoplasm, kidney stones, inflammatory diseases, endometriosis, psychogenic

**Table 13. Etiology, Signs and Symptoms of Common Causes of Dysuria**

<td>E. coli, S. saprophyticus, Proteus mirabilis, Enterobacter, Klebsiella, Pseudomonas</td>
<td>Internal dysuria, fever, chills, flank pain radiating to groin, CVA tenderness, N/V</td>
</tr>
</tbody>
</table>

**Investigations**
- no investigations necessary when history and physical consistent with uncomplicated UTI – treat empirically (urinalysis can be performed when indicated by dipstick or microscopy)
- urinalysis/dipstick: positive for nitrates and leukocytes
- urine R&M: pyuria, bacteriuria, hematuria
- urine C&S
- CBC and differential if suspecting pyelonephritis
  - if vaginal/urethral discharge present: wet mount, Gram stain, KOH test, vaginal pH, culture for yeast and trichomonas, endocervical/urethral swab or urine PCR for N. gonorrhoeae and C. trachomatis
  - radiologic studies and other diagnostic tests if atypical presentation
  - see Pediatrics, P60 for UTI

**Management**
- UTI/cystitis
  - pregnant women with bacteriuria (2-7%) must be treated even if asymptomatic due to increased risk of pyelonephritis, preterm labour, low birth weight, and perinatal mortality; need to follow with monthly urine cultures and repeat if still infected
  - patients with recurrent UTIs (>3/yr) should be considered for prophylactic antibiotics
  - if complicated UTI, patients require longer courses of broader spectrum antibiotics
  - urethritis
    - positive swab or PCR for chlamydia or gonorrhea must be reported to Public Health
    - all patients should return 4-7 d after completion of therapy for clinical evaluation
Epistaxis

- see Otolaryngology, OT26

Erectile Dysfunction

- see Urology, U33

Definition
- consistent or recurrent inability to attain and/or maintain penile erection sufficient for sexual performance of ≥3 mo duration

Epidemiology
- ~20% of men age 40; ~50% of men age 70

Etiology
- organic: vascular (90%) (arterial insufficiency, atherosclerosis), endocrine (low testosterone, DM), anatomic (structural abnormality, e.g. Peyronie’s), neurologic (post-operative, DM), medications (clonidine, antihypertensives, psychotropics)
- psychogenic (10%)

Walsh PC, Campbell MF, Retik AB. Campbell’s Urology, 8th ed. W.B. Saunders, 2002. Table 46-4

History
- comprehensive sexual, medical, and psychosocial history
- time course
  - last satisfactory erection
  - gradual or sudden onset
  - attempts at sexual activity
- quantify
  - presence of morning or night time erections
  - stiffness (scale of 1-10)
  - ability to initiate and maintain an erection with sexual stimulation
  - erection stiffness during sex (scale of 1-10)
- qualify
  - partner or situation specific
  - loss of erection before penetration or climax
  - degree of concentration required to maintain an erection
  - percentage of sexual attempts satisfactory to patient and/or his partner
  - significant bends in penis or pain with erection
  - difficulty with specific positions
  - impact on quality of life and relationship

Investigations
- hypothalamic-pituitary-gonadal axis evaluation: testosterone (free + total), prolactin, LH
- risk factor evaluation: fasting glucose, HbA1c, lipid profile
- others: TSH, CBC, urinalysis
- specialized testing
  - psychological and/or psychiatric consultation
  - in-depth psychosexual and relationship evaluation
  - nocturnal penile tumescence and rigidity (NPTR) assessment
  - vascular diagnostics (e.g. doppler studies, angiography)

The Effect of Lifestyle Modification and Cardiovascular Risk Factor Reduction on Erectile Dysfunction
Arch Intern Med 2011;171:779-1903

Purpose: To evaluate the effectiveness of lifestyle interventions and pharmacotherapy for cardiovascular (CV) risk factors on severity of erectile dysfunction (ED).
Methods: Meta-analysis of RCTs with a follow-up of a minimum of 6 wk, evaluating lifestyle intervention versus pharmacotherapy for CV risk factor reduction. Main outcome measure was weighted mean differences in the International Index of Erectile Dysfunction (IIEF-5) score.
Results: 6 RCTs with a total of 740 participants were included. Lifestyle modifications and pharmacotherapy for CV risk factor reduction were both associated with significant improvements in sexual function based on IIEF-5 scores (weighted mean difference (WMD) 2.36, 95% CI 1.88-2.84). Excluding active trials, lifestyle modification interventions were associated with a statistically significant improvement in sexual function (WMD 2.40, 1.19-3.61).
Conclusion: Lifestyle modifications and pharmacotherapy for CV risk reduction are effective in improving male sexual function.

Reasons for Referral to Urology
- Significant penile anatomic disease
- Younger patient with a history of pelvic or perineal trauma
- Cases requiring vascular or neurosurgical intervention
- Complicated endocrinopathies
- Complicated psychiatric or psychosocial problems
- Patient or physician desire for further evaluation
Management

Fatigue

Definition

- can describe difficulty or inability to initiate activity, maintain activity, or difficulty with concentration/memory
- try to determine what the patient means e.g. excessive sleepiness, muscle weakness, decreased exercise tolerance, mood concerns

Epidemiology

- 25% of office visits to family physicians
  - peaks in ages 20-40
  - F:M = 3-4:1
- 50% have associated psychological complaints/problems, especially if <6 mo duration

Differential Diagnosis

Table 17. Differential Diagnosis of Fatigue: PS VINDICATE

Common causes are in **bold**

Investigations

- psychosocial causes are common, so usually minimal investigation is warranted
- physical causes of fatigue usually have associated symptoms/signs that can be elicited from a focused history and physical exam
- investigations are guided by history and physical exam and may include:
  - CBC and differential, electrolytes, BUN, Cr, ESR, glucose, TSH, ferritin, vitamin B₁₂, serum protein electrophoresis, Bence-Jones protein, albumin, AST, ALT, ALP, bilirubin, calcium, phosphate, ANA, β-hCG
  - urinalysis, CXR, ECG
  - additional tests: serologies (Lyme disease, hepatitis B and C screen, HIV, ANA) and Mantoux skin tests
Treatment
- treat underlying cause
- if etiology cannot be identified (1/3 of patients)
  - reassurance and follow-up, especially with fatigue of psychogenic etiology
  - supportive counselling, behavioural, or group therapy
  - encourage patient to stay physically active to maximize function
  - review all medications, OTC, and herbal remedies for drug-drug interactions and side effects
- prognosis: after 1 yr, 40% are no longer fatigued

CHRONIC FATIGUE SYNDROME

Definition (CDC 2006) – must meet both criteria
1. new or definite onset of unexplained, clinically evaluated, persistent or relapsing chronic fatigue, not relieved by rest, which results in occupational, educational, social, or personal dysfunction
2. concurrent presence of ≥4 of the following symptoms for a minimum of 6 mo
  - impairment of short-term memory or concentration, severe enough to cause significant decline in function
  - sore throat
  - tender cervical or axillary lymph nodes
  - muscle pain
  - multi-joint pain with no swelling or redness
  - new headache
  - unrefreshing sleep
  - post-exertion malaise lasting >24 h
- exclusion criteria: medical conditions that may explain the fatigue, certain psychiatric disorders (depression with psychotic or melancholic features, schizophrenia, eating disorders), substance abuse, severe obesity (BMI >45)

Epidemiology
- F>M, Caucasians > other groups, majority in their 30s
- found in <5% of patients presenting with fatigue

Etiology
- unknown, likely multifactorial
- may include infectious agents, immunological factors, neurohormonal factors, and/or nutritional deficiency

Investigations
- no specific diagnostic laboratory tests

Treatment
- promote sleep hygiene
- provide support and reassurance that most patients improve over time
- non-pharmacological
  - regular physical activity, optimal diet, psychotherapy (e.g. CBT), family therapy, support groups
- pharmacological
  - to relieve symptoms: e.g. antidepressants, anxiolytics, NSAIDs, antimicrobials, antiallergy therapy, antihypotensive therapy

Fever

- see Pediatrics, P49

Definition
- oral temperature >37.2°C (AM), 37.7°C (PM)
- fever in children under 2 must be a rectal temperature for accuracy
- TM not accurate for measurement until child is >5 yr

Table 18. Differential Diagnosis of Fever

<table>

History
- fever
  - peak temperature, thermometer, route, duration
  - time of day
  - response to antipyretics
- systemic symptoms
- weight loss, fatigue, rash, arthralgia, night sweats
- symptoms of possible source
  - UTI/pyelonephritis: dysuria, foul-smelling urine, incontinence, frequency, hematuria, flank pain
  - URTI: cough, coryza, ear pain
  - meningitis: headache, confusion, stiff neck, rash
  - osteomyelitis: bone pain
  - skin: purulent discharge
  - PID: discharge, dyspareunia, lower abdominal pain
  - gastroenteritis: abdominal pain, diarrhea, blood per rectum, vomit
  - medications
    - PE/DVT: swollen legs, pain in calf, SOB, pleuritic chest pain
    - history of cancer/family history of cancer
- infectious contacts
- travel history, camping, daycare, contact with TB, foodborne, animals

Possible Investigations
- CBC and differential, blood culture, urine culture, urinalysis
- stool O&P, Gram stain, culture
- CXR, Mantoux skin test, sputum culture
- lumbar puncture

Management
- increase fluid intake
- general: sponge bath, light clothing
- acetaminophen/ibuprofen as needed
- treat underlying cause

Headache

Primary Headaches
- see Neurology, N44

Secondary Headaches
- caused by underlying organic disease
- account for <10% of all headaches, may be life-threatening

Etiology
- drug: drug withdrawal, medication overuse, drug side effect, and carbon monoxide
- infectious: meningitis, encephalitis, abscess
- vascular: aneurysm, stroke, subarachnoid hemorrhage, hypertension, and temporal arteritis
- endocrine: thyroid disease, pheochromocytoma
- neoplastic: tumour
- trauma: TMJ injury, c-spine injury, head injury, subdural hematoma, and subarachnoid hemorrhage
- other: serious ophthalmological and otolaryngological causes

Investigations
- indicated only when red flags are present and may include:
  - CBC for suspected systemic or intracranial infection
  - ESR for suspected temporal arteritis
  - neuroimaging (CT or MRI) to rule out intracranial pathology
  - CSF analysis for suspected intracranial hemorrhage, infection

Management
- based on underlying disorder
- analgesics may provide symptomatic relief

Acupuncture for Migraine Prophylaxis
Cochrane Database Syst Rev 2016:6:CD001218

Purpose: To investigate whether acupuncture is more effective than no prophylactic treatment, routine care only or sham acupuncture, and whether it is as effective as prophylactic pharmacological treatment, in terms of reducing headache frequency in adults with episodic migraine.

Methods: Meta-analysis of RCTs with a minimum of an 8 wk duration, comparing acupuncture-intervention with a no-acupuncture control (no prophylaxis, routine care, sham, or pharmacological prophylaxis).

Results: 22 trials with 4985 participants were included. Acupuncture was associated with moderate headache frequency reduction compared to no acupuncture (standardized mean difference (SMD) 4.59, 95% CI -0.81 to 9.99, and a reduction of 15% in headache frequency for 41% and 17% of participants receiving acupuncture and no acupuncture, respectively (pooled risk ratio (RR) 2.34, 2.08 to 2.60; number needed to treat (NNT) 4.22, 3.99 to 4.77, number needed to treat (NNT) 4.20, 3.98 to 4.76). Acupuncture showed a small but statistically significant reduction over sham both post-treatment (SMD -0.19, 95% CI -0.38 to -0.00) and post-follow-up (SMD -0.11, 95% CI -0.30 to 0.08), with 9.5% headache frequency reduction being achieved in 58% versus 47% of those receiving acupuncture and sham, respectively (pooled RR 1.23, 95% CI 1.11 to 1.36; NNT 17, 9 to 20); these numbers were 50% and 42%, respectively, post-follow-up (pooled RR 1.13, 95% CI 1.03 to 1.23; NNT 10, 6 to 18). Number of participants dropping out and reporting adverse effects did not differ significantly between acupuncture and sham groups. Compared to pharmacological prophylaxis, a significant reduction in migraine frequency was noted with drugs (SMD -0.25, 95% CI -0.39 to 0.10, but the significance was not maintained at follow-up. After 6 mo, headache frequency was halved in 59% of patients receiving acupuncture and 54% receiving prophylactic drugs (pooled RR 1.11, 95% CI 1.03 to 1.20). Those receiving acupuncture were less likely to drop out due to adverse effects or to report adverse events than those receiving drugs. Conclusion: Adding acupuncture to symptomatic treatment of attacks reduces frequency of headaches. Acupuncture is more effective than sham, and is similarly effective to pharmacological interventions for migraine prophylaxis.

Migraine Screen
POUND
Pulsatile quality
Over 4-72 h
Unilateral
Nausea and vomiting
Disabling intensity
if ≥4 present then a diagnosis is likely (+LR = 24)

Headache Red Flags
SNOOP
Systemic symptoms of illness
- fever
- anticoagulation
- pregnancy
- cancer
Neurologic signs/symptoms
- impaired mental status
- neck stiffness
- seizures
- focal neurological deficits
Onset
- sudden and severe
- new headache after age 50
Other associated conditions
- following head trauma
- awaken patient from sleep
- jaw claudication
- scalp tenderness
- worse with exercise, sexual activity or Valsalva
Prior headache history
- different pattern
- rapidly progressing in severity/frequency
Hearing Impairment

• see Otolaryngology, OT7

Definition
• hearing impairment: a raised hearing threshold measured as decibels of hearing loss relative to the normal population at specific frequencies
• hearing disability: hearing impairment that interferes with performing daily tasks

Epidemiology
• prevalence increases with age (6% of 35-44 yr old, 43% of 65-84 yr old)
• 90% of age-related hearing loss (presbycusis) is sensorineural
• hearing loss detectable by audiology is present in greater than 1/3 of people >65 yr

Classification
• conductive (external sound does not reach the middle ear)
• sensorineural involving the inner ear, cochlea, or auditory nerve
• mixed

Assessment
• infants: universal newborn hearing screening program
• elderly
  • whispered-voice test
    • examiner stand 0.6 metres behind the patient, whispers a combination of 6 letters/numbers, and asks the patient to repeat the sequence; test 1 ear at a time while masking the non-test ear simultaneously
  • tuning fork test (to distinguish conductive from sensorineural hearing loss)
    • Rinne and Weber (not for general screening)
  • formal audiologic assessment
  • pure tone, air, and bone conduction testing
  • speech audiometry
  • impedance audiometry

Management
• counsel about noise control and hearing protection programs (Grade A evidence)
• perform investigations in patients with unexplained sensorineural hearing loss
  • blood sugar, CBC and differential, TSH, syphilis testing
  • consider a CT/MRI for patients with progressive asymmetric sensorineural hearing loss to exclude vestibular schwannoma (acoustic neuroma)
• refer patients who
  • exhibit hearing loss for a complete audiological examination
  • have an unknown etiology to an ENT specialist
  • experience sudden sensorineural hearing loss to an ENT specialist (urgent, requires oral steroid Tx)
• treatment: hearing amplification (e.g. hearing aids), assistive listening devices, and cochlear implants can dramatically improve quality of life

Hypertension

Hypertension Guidelines are reviewed and updated annually, for up-to-date recommendations, please see http://guidelines.hypertension.ca/

Epidemiology
• 22% of Canadian adults suffer from HTN (prevalence is 52% in the 60-70 age group)
• lifetime risk of developing hypertension is approximately 90%
• 64% of Canadians who have HTN are treated and controlled, while 17% are unaware that they have HTN
• 3rd leading risk factor associated with death
• risk factor for CAD, CHF, cerebrovascular disease, renal failure, peripheral vascular disease

Definitions
• HTN
  • BP ≥140/90 mmHg (OBPM) ≥135/85 (ABPM/AOBP)
• isolated systolic HTN
  • sBP ≥140 and dBP <90
  • associated with progressive reduction in vascular compliance
  • usually begins in 5th decade
• hypertensive urgency
  • sBP >210 or dBP >120 with minimal or no target-organ damage
• hypertensive emergency
  • severe HTN (dBP >120) + acute target-organ damage
• accelerated HTN
  • significant recent increase in BP over previous hypertensive levels associated with evidence of vascular damage on fundoscopy, but without papilledema
• malignant HTN
  • sufficient elevation in BP to cause papilledema and other manifestations of vascular damage (retinal hemorrhages, bulging discs, mental status changes, increasing creatinine)
• white coat HTN
  • high clinic BP with normal home BP and 24 h ambulatory BP, caused by anxiety in clinic
• masked HTN
  • normal clinic BP with high BP in home and/or ambulatory setting, often provoked by anxiety, job stress, exercise

Etiology
• essential hypertension (90%, undetermined cause)
• secondary hypertension (10%, known cause)

Predisposing Factors
• family history
• obesity (especially abdominal)
• alcohol consumption
• stress
• sedentary lifestyle
• smoking
• male
• age >30
• excessive salt intake/fatty diet
• African American ancestry
• dyslipidemia

Investigations
• for all patients with HTN:
  • electrolytes, Cr, fasting glucose and/or HbA1c, lipid profile, 12-lead ECG, urinalysis
  • self-measurement of BP at home is encouraged (recommended devices listed at www.hypertension.ca)
• for specific patient etiology:
  • DM or chronic kidney disease: urinary protein excretion
  • if suspected renovascular HTN: renal ultrasound, captopril renal scan (if GFR >60 mL/min), MRA/CTA (if normal renal function)
  • if suspected endocrine cause: plasma aldosterone, plasma renin (aldosterone-to-renin ratio)
  • measured from morning samples taken from patients in sitting position after resting 15 min
  • discontinue aldosterone antagonists, ARBs, β-blockers, and clonidine prior to testing
  • if suspected pheochromocytoma: 24 h urine for metanephrines and creatinine
  • if suspected LV dysfunction: echocardiogram

Diagnosis
• all Canadian adults should have BP assessed at all appropriate clinical visits, oscillometric preferred to manual
**Figure 12. Diagnostic algorithm for hypertension in adults**

**Treatment**
- treat to target BP: <140/90 mmHg, <130/80 mmHg if DM
- optimum management of HTN requires assessment of overall cardiac risk
- adherence to lifestyle modification and pharmacotherapy should be assessed at each visit
- single pill combinations should be used as first line treatment (regardless of the extent of BP elevation)
- lifestyle modification (in all HTN patients – may be sufficient treatment in patients with stage 1 HTN (140-159/90-99))
  - diet
    - follow Canada’s Guide to Healthy Eating (see Nutrition, FM9) and Dietary Approaches to Stop Hypertension (DASH)
    - limit daily sodium intake to 5 g or 87 mmol/d
    - potassium/magnesium/calcium supplementations are NOT recommended for HTN but an increase in dietary potassium may help
    - moderate intensity dynamic exercise: 30-60 min, 4-7x/wk; higher intensity exercise is not more effective
    - smoking cessation
    - low-risk alcohol consumption (see Alcohol, FM12)
    - work towards a healthy BMI (18.5-24.9 kg/m²) and waist circumference (<102 cm for men, <88 cm for women)
    - individualized cognitive behavioural interventions for stress management
  - pharmacological
    - indications for therapy (caution with elderly patients):
      - dBP ≥90 mmHg with target organ damage or independent cardiovascular risk factors
      - dBP ≥100 mmHg or sBP ≥160 mmHg without target organ damage or cardiovascular risk factors
      - sBP ≥140 with target organ damage
      - sBP >130 for high risk populations (Framingham Risk >20%, age >50)
    - first line antihypertensives (consider a single pill combination therapy)
    - combination therapy principles:
      - if there is an inadequate response to therapy, consider adding another first line antihypertensive
      - avoid combining a non-DHP CCB with a β-blocker or an ACEI with an ARB
      - monitor potassium and creatinine when administering an ACEI/ARB with a potassium sparing diuretic

<thead>
<tr>
<th>Condition or Risk Factor</th>
<th>Recommended Drugs</th>
<th>Alternative Drugs</th>
<th>Not Recommended/Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Isoled Diastolic HTN with or without Systolic HTN</strong></td>
<td>Monotherapy or SPC Recommended monotherapy choices include thiazide/thiazide-like diuretics (with longer-acting diuretics preferred), B-blockers, ACEI, ARBs, or long-acting CCBs. Recommended SPC choices include combinations of an ACEI with CCB, ARB with CCB, or ACEI/ARB with a diuretic. (Consider ASA and statins in selected patients)</td>
<td>Combinations of first-line drugs</td>
<td>Not recommended for monotherapy; a-blockers, β-blocker in those ≥80 yr of age, ACEI in black people. Hypokalemia should be avoided in those prescribed diuretics. ACEI, ARBs and direct renin inhibitors are potential teratogens, and caution is required if prescribing to women with childbearing potential. Combination of an ACEI with an ARB is not recommended</td>
</tr>
<tr>
<td><strong>Isolated Systolic HTN without other compelling indications</strong></td>
<td>Thiazide diuretic, ARB, or long acting dihydropyridine CCB</td>
<td>Combinations of first-line drugs</td>
<td>Same as above</td>
</tr>
<tr>
<td><strong>CAD</strong></td>
<td>ACEI or ARB; β-blockers or CCB for patients with stable angina</td>
<td>When combination therapy for high risk patients, ACEI/DHP CCB is preferred</td>
<td>Avoid short-acting nifedipine. Combination of an ACEI with an ARB is specifically not recommended. Exercise caution when lowering sBP to target if dBP is ≤80 mmHg, especially in patients with LVH. Non-dihydropyridine CCBs should not be used with concomitant heart failure</td>
</tr>
<tr>
<td><strong>Recent MI</strong></td>
<td>β-blocker and ACEI (ARB if cannot tolerate ACEI)</td>
<td>Long-acting CCB if β-blocker contraindicated or not effective.</td>
<td></td>
</tr>
<tr>
<td><strong>Left Ventricular Hypertrophy</strong></td>
<td>ACEI, ARB, thiazide/thiazide-like diuretics, or long-acting CCB</td>
<td>Combination of additional agents</td>
<td>Hydralazine and minoxidil can increase LVH, thus not recommended</td>
</tr>
<tr>
<td><strong>Cerebrovascular Disease</strong> (stoke/TIA)</td>
<td>ACEI and thiazide/thiazide-like diuretic combination</td>
<td>Combination of additional agents</td>
<td>Treatment of HTN should not be routinely undertaken in acute stroke unless extreme BP elevation. ACEI and ARB combination after a stroke is not recommended</td>
</tr>
<tr>
<td><strong>Heart Failure</strong></td>
<td>ACEI (ARB if ACEI intolerant) and β-blockers Aldosterone antagonists (mineralocorticoid receptor antagonists) may be added for patients with a recent cardiovascular hospitalization, acute myocardial infarction, elevated BNP or NT-proBNP level, or NYHA Class II to IV symptoms</td>
<td>ARB in addition to ACEI Hydralazine/dioxicarb diurate combination if ARB or ACEI not tolerated/contraindicated Thiazide/thiazide-like or loop diuretics are recommended as additive therapy. DHP CCB can also be used</td>
<td>A combined ARB/neprilysin inhibitor is recommended (in place of an ACEI or ARB) in symptomatic patients with hypertension and HFREF on standard guideline-based therapies. Titrate doses of ACEI and ARBs to those used in clinical trials. Carefully monitor potassium and renal function if combining any of ACEI, ARB and/or aldosterone antagonist</td>
</tr>
<tr>
<td><strong>Dyslipidemias</strong></td>
<td>Does not affect initial treatment recommendations</td>
<td>Combination of additional agents</td>
<td></td>
</tr>
<tr>
<td><strong>DM with Albuminuria (ACR &gt;2.0 mg/mmol renal disease, CVD or additional CV risk factors)</strong></td>
<td>ACEI or ARB</td>
<td>Addition of a dihydropyridine CCB is preferred over a thiazide/thiazide-like diuretic</td>
<td>A loop diuretic could be considered in hypertensive chronic kidney disease patients with extracellular fluid volume overload</td>
</tr>
<tr>
<td><strong>DM without Albuminuria (criteria listed above)</strong></td>
<td>ACEI, ARB, DHP CCB, or thiazide/thiazide-like diuretics</td>
<td>Combination of first-line drugs</td>
<td>Normal urine microalbumin to creatinine ratio &lt;2.0 mg/mmol</td>
</tr>
<tr>
<td><strong>Non-Diabetic Chronic Kidney Disease with Proteinuria (urinary protein &gt;500 mg/24 h or ACR &gt;30 mg/mmol)</strong></td>
<td>ACEI (ARB if ACEI intolerant), if there is proteinuria Diuretics as additive therapy</td>
<td>Combinations of additional agents</td>
<td>Patients on an ACEI or ARB should have careful monitoring of renal function and potassium. ACEI and ARB combinations are not recommended in patients without proteinuria</td>
</tr>
<tr>
<td><strong>Renovascular Disease</strong></td>
<td>Does not affect initial treatment recommendations Atherosclerotic renal artery stenosis should be primarily managed medically, while revascularization should be considered for renal fibromuscular dysplasia</td>
<td>Combinations of additional agents</td>
<td>Caution in using ACEI or ARB if bilateral renal artery stenosis or unilateral disease with solitary kidney Renal artery angioplasty and stenting could be considered for patients with renal artery stenosis and complicated, uncontrolled hypertension</td>
</tr>

**References:**
- Toronto Notes 2020
- FM36 Family Medicine
- Common Presenting Problems

**Table 21. Considerations in the Individualization of Pharmacological Therapy in Adults (continued)**

- How to Combine Antihypertensive Medications (in general)
  - ACEI
  - β-blocker
  - Diuretic
  - CCB
  - Aldosterone antagonist

**Conclusion:** Thiazide-type diuretics are superior to CCB and ACEI for preventing one or more major forms of CVD, with similar risks of death and non-fatal MI.

**Purpose:** To evaluate whether calcium channel blocker or angiotensin-converting enzyme inhibitors lower incidence of coronary heart disease (CHD) or other cardiovascular disease (CVD) relative to treatment with a diuretic.

**Methods:** Randomized, double-blind, active-controlled clinical trial with mean follow-up of 4.9 yr. Participants with stage 1 or 2 hypertension (HTN) and at least 1 other CHD risk factor were included, and randomized to receive chlorthalidone (12.5-25 mg/d), amlodipine (2.5-10mg/d), or lisinopril (10-40 mg/d). Target BP was <140/90 mmHg, achieved by titrating the assigned study drug, and adding open-label agents when necessary. The primary outcome was combined fatal CHD or non-fatal MI. Secondary outcomes were all-cause mortality, stroke, combined CHD, and combined CV death.

**Results:** 33,887 participants (mean age 67 yr, 52% male, 47% white) were included. There were no significant differences in either the primary outcome or all-cause mortality between treatment groups. For amlodipine vs. chlorthalidone, secondary outcomes were similar except for a higher 6 yr rate of heart failure with amlodipine (10.2% vs. 7.7%, p<0.001). For lisinopril vs. chlorthalidone, lisinopril had higher 6 yr rates of combined CV death (33.3% vs. 30.9%, p<0.001), stroke (8.3% vs. 6.6%, p=0.02) and heart failure (8.7% vs. 7.7%, p<0.001).

**Conclusion:** Thiazide-type diuretics are superior to CCB and ACEI for preventing one or more major forms of CVD, with similar risks of death and non-fatal MI.
Follow-Up
- assess and encourage adherence to pharmacological and non-pharmacological therapy at every visit
- lifestyle modification q3-6mo
- pharmacological
  - follow-up q1-2mo until BP under target for 2 consecutive visits. q3-6mo once at target BP
  - follow-up frequently for patients with symptomatic/severe HTN, antihypertensive drug intolerance, target organ damage
- referral is indicated for cases of refractory HTN, suspected secondary causes, or worsening renal failure
- hospitalization is indicated for malignant HTN

Joint Pain
- see Rheumatology, RH3

History
- number of joints involved: monoarticular, oligoarticular, polyarticular
- pattern of joints involved: symmetrical vs. asymmetrical, large vs. small joints, axial skeleton
- onset: acute vs. chronic (>6 wk)
- morning stiffness (duration) vs. worse at end of day with activity
- PMHx
  - trauma, infection, medications (steroids, diuretics)
  - comorbidities: DM, renal insufficiency (gout), psoriatic arthritis, myeloma, osteoporosis, and OA
  - FHx of arthritis, autoimmune disease
- ROS: constitutional symptoms (neoplasm, septic arthropathy), myalgia, skin/eye/nail/hand changes, and GI/GU changes

Physical Exam
- vitals
- specific joint exams to affected areas
- systemic features (skin, nails, eyes, hands)

Investigations (Guided by the History and Physical Exam)
- general: CBC and differential, electrolytes, Cr
- acute phase reactants: ESR, CRP
- complement (C3, C4)
- urinalysis to detect disease complications (proteinuria, active sediment)
- serology (ANA, anti-dsDNA, HLA-B27, anti-Jo-1, anti-Sm, anti-Ro, RhF, and anti-CCP, etc.)
- synovial fluid analysis (cell count + differential, culture, Gram stain, microscopy)
- radiology (plain film, CT, MRI, U/S, bone densitometry, bone scan)

Treatment
- tailor therapy depending on the specific cause
- non-pharmacological: patient education, lifestyle modification, assisted devices, physiotherapy, occupational therapy
- pharmacological: analgesia (acetaminophen, NSAIDs), anti-inflammatory (DMARDs, steroids), antibiotics

Low Back Pain
- see Orthopedic Surgery, OR26

Definition
- acute: <6 wk
- subacute: 6-12 wk
- chronic: >12 wk

Epidemiology
- 5th most common reason for visiting a physician
- lifetime prevalence: 90%, and peak prevalence: age 45-60
- largest WSIB category and most common cause of disability for individuals <45 yr old
- 90% resolve in 6 wk, <5% become chronic
Etiology
- source of pain can be local, radicular, referred, or related to a psychiatric illness
- 98% are mechanical causes (worse with movement, better with rest)
  - soft tissue: sprain (ligament), strain (muscle)
  - spine: facet joint/disc degeneration, disc herniation, spinal stenosis (e.g. spondylolisthesis), spondylolisthesis, compression fracture
  - other: pregnancy
- 2% are non-mechanical causes
  - surgical emergencies
    - cauda equina syndrome (areflexia, lower extremity weakness, saddle anesthesia, fecal incontinence, urinary retention)
- AAA (pulsatile abdominal mass)
- medical conditions
  - neoplastic: primary, metastatic, multiple myeloma
  - infectious: osteomyelitis, TB
  - metabolic: osteoporosis, osteomalacia, Paget’s disease
  - rheumatologic: ankylosing spondylitis, polymyalgia rheumatica
  - referred pain: perforated ulcer, pancreatitis, pyelonephritis, ectopic pregnancy, herpes zoster

Physical Exam
- inspection: curvature, posture, gait
- palpation: bony deformities/tenderness, paraspinal muscle bulk/tenderness, trigger points
  - percussion of spine to elicit pain due to fracture or infection
- range of motion and peripheral pulses
- neurologic exam for L4/L5/S1 helps determine level of spinal involvement (power, reflexes, sensation)
- special tests
  - straight leg raise (positive if pain at <70 degrees and aggravated by ankle dorsiflexion), positive test is indicative of sciatica
  - crossed straight leg raise (raising of uninvolved leg elicits pain in leg with sciatica), more specific than straight leg raise
  - femoral stretch test (patient prone, knee flexed, examiner extends hip) to diagnose L4 radiculopathy

Investigations
- plain films not recommended in initial evaluation
- if infection/cancer suspected: CBC, ESR
- if neurologic deficits worsening or infection/cancer suspected: consider CT or MRI
**A Summary of the Guideline for the Evidence-Informed Primary Care Management of Low Back Pain**

This evidence-informed guideline is for non-specific, non-malignant low back pain in adults only.

### Red Flags

- Help identify rare, but potentially serious conditions. They include:
  - Features of Cauda Equina Syndrome including sudden onset of loss of bladder/bowel control, saddle anesthesia (EMERGENCY)
  - Severe worsening pain, especially at night or when lying down (URGENT)
  - Significant trauma (URGENT)
  - Weight loss, history of cancer (URGENT)
  - Use of steroids or intravenous drugs (URGENT)
  - Patient with first episode over age of 50 yr, especially over 65 (SOON)
  - Widespread neurological signs (SOON)

**EMERGENCY** — referral within hours

**URGENT** — referral within 24-48 h

**SOON** — referral within weeks

### Yellow Flags

Indicate psychosocial barriers to recovery. They include:
- Belief that pain and activity are harmful
- ‘Sickness behaviours’ (like extended rest)
- Low or negative mood, social withdrawal
- Treatment expectations that do not fit best practice
- Problems with claim and compensation
- History of back pain, time-off, other claims
- Problems at work, poor job satisfaction
- Heavy work, unsociable hours (shift work)
- Overprotective family or lack of support

### Conduct a full assessment including:

- History taking
- Physical and neurological exam
- Evaluation of Red Flags
- Psychosocial risk factors/Yellow Flags

### Pattern 1: Constant/intermittent

- Pain changes with back movement/position
- Leg pain can improve but not disappear
- Improves with specific back position
- No better with position changes
- Disc pain

**Medication as required:**
- Acetaminophen + NSAIDs

### Pattern 2: Always intermittent

- Pain improves with specific back position
- No better with position changes
- Facet joint pain

**Medication as required:**
- Acetaminophen

### Pattern 3: Fast responder

- Leg pain can improve but not disappear
- No better with position changes
- Supine “Z” lie

**Medication as required:**
- Acetaminophen + NSAIDs

### Pattern 4: Slow responder

- Leg pain can improve but not disappear
- Worsen with flexion
- Improves with specific back position
- Night lumbar roll

**Medication as required:**
- Acetaminophen + NSAIDs

### Table 21. Approach to Non-Traumatic Low Back Pain

**Figure 13. Low back pain treatment**

**Table 21. Approach to Non-Traumatic Low Back Pain**

- **Back Dominant (Pain greatest above gluteal fold)**
- **Leg Dominant (Pain greatest below gluteal fold)**
- **Pattern 4 (Worse with activity)**
- **Medication as required:**
  - Acetaminophen + NSAIDs

---

**Spinal Manipulative Therapy (SMT) for Acute Low Back Pain**

**Cochrane Database Syst Rev 2012;9:CD008880**

**Purpose:** To evaluate the effect of spinal manipulation therapy for non-specific low back pain.

**Methods:** Meta-analysis of RCTs examining effectiveness of SMT (hands-on therapy directed towards spine, including both manipulation and mobilization) in adults with acute low back pain (pain lasting ≥ 4 wk).

**Results:** 13 RCTs were identified, comparing massage therapy to other active or sham treatments. Massage was superior for pain and function on both short and long-term follow-ups relative to sham treatment. It was similar to exercises, and superior to joint mobilization, relaxation therapy, physical therapy, acupuncture and self-care education. Benefits lasted at least 1 yr post-treatment. Acupuncture massage was associated with better results than classic (Swedish) massage, and Thai massage produced similar results to the classic massage.

**Conclusions:** Massage may be beneficial for subacute and chronic non-specific low back pain, especially in combination with exercise and education; it is more effective than classic massage.

---

**Massage for Low Back Pain**

**Cochrane Database Syst Rev 2012;9:CD008880**

**Purpose:** To evaluate the effect of massage therapy for non-specific low back pain.

**Methods:** Meta-analysis of randomized or quasi-randomized trials evaluating use of any massage modality (hands or mechanical device) as a treatment for non-specific low back pain.

**Results:** 13 RCTs were identified, comparing massage therapy to other active or sham treatments. Massage was superior for pain and function on both short and long-term follow-ups relative to sham treatment. It was similar to exercises, and superior to joint mobilization, relaxation therapy, physical therapy, acupuncture and self-care education. Benefits lasted at least 1 yr post-treatment. Acupuncture massage was associated with better results than classic (Swedish) massage, and Thai massage produced similar results to the classic massage.

**Conclusions:** Massage may be beneficial for subacute and chronic non-specific low back pain, especially in combination with exercise and education; it is more effective than classic massage.
Menopause/Hormone Replacement Therapy

- see Gynecology, GY33

Epidemiology
- mean age of menopause = 51.4 yr

Clinical Features
- associated with estrogen deprivation
- urogenital tract: atrophy, vaginal dryness/itching, urinary frequency/urgency/incontinence, bleeding
- vascular: vasomotor instability (e.g. hot flashes), increased risk of heart disease
- bones: bone loss, joint/muscle/back pain, fractures, loss of height
- brain: depression, irritability, mood swings, memory loss

Management
- non-pharmacological management: encourage physical exercise, smoking cessation, and a balanced diet with adequate intake/supplementation of calcium (1200 mg/d) and vitamin D (1000 IU/d)
- pharmacological management:
  - hormone replacement therapy (HRT)
    - initiation of HRT requires a thorough discussion of short- and long-term benefits and risks
    - prescribe for moderate to severe symptoms for no longer than 5 yr; routine use is not recommended
    - regimens: cyclic or continuous estrogen-progestin, estrogen only (if no uterus, patch/gel/cream/ ring/vaginal tablet)
    - advantages: decreases risk of osteoporotic fractures, colorectal cancer
    - disadvantages: increases risk of breast cancer, coronary heart disease, stroke, DVT, and PE
  - venlafaxine, SSRIs, or gabapentin to ease vasomotor instability

Osteoarthritis

- see Rheumatology, RH5

Epidemiology
- most common form of arthritis seen in primary care
- prevalence is 10-12% and increases with age
- results in long-term disability in 2-3% of patients with OA
- almost everyone over the age of 65 shows signs of OA on x-ray, but only 33% of these individuals will be symptomatic

Clinical Features
- joint pain with activity, improved with rest, morning stiffness or gelling <30 min
- deformity, bony enlargement, crepitus, limitation of movement, peri-articular muscle atrophy
- usually affects distal joints of hands, spine, hips, and knees

Investigations
- no laboratory tests for the diagnosis of OA
- hallmark radiographic features: joint space narrowing, subchondral sclerosis, subchondral cysts, osteophytes

Management
- goals: relieve pain, preserve joint motion and function, prevent further injury
- conservative
  - patient education, weight loss, low-impact exercise (OT/PT), assistive devices (e.g. canes, orthotics)
  - consider comorbidities such as PUD, HTN, IHD, hepatic disease, and renal disease
  - medications do not alter natural course of OA
- 1st line: acetaminophen up to 4 g/d (OA is not an inflammatory disorder)
- 2nd line: NSAIDs (COX-2 selective) in low doses for short durations
- 3rd line: combination analgesics (e.g. acetaminophen and codeine)
- other pharmacological adjuncts:
  - intra-articular corticosteroid or hyaluronic acid injections
  - topical NSAIDs (diclofenac)
  - capsaicin cream
  - oral glucosamine
- surgery
  - consider if persistent significant pain and functional impairment despite optimal pharmacotherapy (e.g. debridement, osteotomy, total joint arthroplasty)
Osteoporosis

- see Endocrinology, E43

**Encourage basic bone health for all individuals over age 50, including regular active weight-bearing exercise, calcium (diet and supplements) 1200 mg daily, vitamin D 800-2000 IU (20-50 µg) daily and fall-prevention strategies.**

**Epidemiology**
- for current guidelines and tools see www.osteoporosis.ca
- age-related disease characterized by decreased bone mass and increased susceptibility to fractures
- affects 1 in 4 Canadian women and 1 in 8 Canadian men

**Approach to Clinical Assessment**
- identify risk factors on history and physical examination
- **history**
  - prior falls, fragility fractures, parental hip fractures, and gait or balance issues
  - glucocorticoid use
  - smoking and alcohol intake (≥3 units/d)
  - rheumatoid arthritis
- **physical examination**
  - height annually (prospective loss >2 cm or historical loss >6 cm) and weight (weight loss >10% since age 25)
  - rib-to-pelvis distance ≤2 fingers' breadth
  - occiput-to-wall distance >5 cm
  - assess fall risk by ability to get up from chair without support with arms, and walking several steps and return

**How Much Calcium Do We Need?**

<table>
<thead>
<tr>
<th>Age</th>
<th>Calcium Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-3</td>
<td>310 mg</td>
</tr>
<tr>
<td>4-8</td>

</tr>
<tr>
<td>Pregnant</td>
<td>1200 mg</td>
</tr>
<tr>
<td>Lactating</td>
<td>1000 mg</td>
</tr>
</tbody>
</table>

**Calcium Content of Common Foods**

- 1 cup milk = 300 mg
- 1 cup yogurt = 332 mg
- 1 medium orange = 50 mg

**Disorders Strongly Associated with Osteoporosis Include:**
- Primary hyperparathyroidism, type 1 DM, osteogenesis imperfecta, uncontrolled hyperparathyroidism, hypogonadism or premature menopause (<45 yr).
- Cushing's disease, chronic malnutrition or malabsorption, chronic liver disease, COPD, and chronic inflammatory conditions (e.g., IBD)

**10 Yr Fracture Risk Assessment**

FRAX (WHO Fracture Risk Assessment Tool) and CAROC (Canadian Association of Radiologists and Osteoporosis Canada) have been validated in the Canadian Population.

FRAX and CAROC are available online from: https://www.osteoporosis.ca/health-care-professionals/clinical-tools-and-resources/

**Vitamin D Content in Food**
- Milk fortified with vitamin D contains 100 IU per 250 mL glass.
- Foods such as margarine, eggs, chicken livers, salmon, sardines, herrings, mackerel, swordfish, and fish oils (halibut and cod liver oils) all contain small amounts; supplementation is necessary to obtain adequate levels as dietary intake has minimal impact.
- Most multivitamins provide 400 IU's of vitamin D3.
Investigations
- CBC, Cr, corrected Ca²⁺, ALP, TSH, 25-OH-D (after 3-4 mo of adequate supplementation), and serum protein electrophoresis if there are vertebral fractures

Indications for Bone Mineral Density Testing and Management
- see Endocrinology, E43

Rash
- see Dermatology, D13

Sexually Transmitted Infections
- see Gynecology, GY26

Definition
- diverse group of infections caused by multiple microbial pathogens
- transmitted by either secretions or fluids from mucosal surfaces

Epidemiology
- high incidence rates worldwide
- Canadian prevalence in clinical practice
  - common: chlamydia (most common), gonorrhea (2nd most common), HPV, genital herpes
  - less common: hepatitis B, HIV, syphilis, trichomoniasis
  - rare: chancroid, granuloma inguinale, lymphogranuloma venereum
  - non-sexually transmitted genital tract infections: vulvovaginal candidiasis (VVC), bacterial vaginosis (BV)
- three most common infections associated with vaginal discharge in adult women are BV, VVC, and trichomoniasis

History
- sexual history
  - age of first intercourse, sexual orientation, sexual activity (oral, anal, and/or vaginal intercourse), sexual activity during travel
  - total number of partners in the past year/month/week and duration of involvement with each
  - STI history
    - STI awareness, contraception, previous STIs and testing (including Pap tests), partner communication regarding STIs
    - local symptoms such as burning, itching, discharge, sores, vesicles, testicular pain, dysuria, abdominal pain
    - systemic symptoms such as fever, lymphadenopathy, arthralgia

Investigations/Screening
- individuals at increased risk should be screened for chlamydia, gonorrhea, hepatitis B, HIV, and syphilis
- Pap test if none performed in preceding 3 yr

Management
- primary prevention is vastly more effective than treating STIs and their sequelae
- offer hepatitis B vaccine if not immune
- offer Gardasil® to women over 9 yr
- discuss STI risk factors (e.g. decreasing the number of sexual partners)
- direct advice to ALWAYS use condoms or to abstain from intercourse
  - condoms are not 100% effective against HPV or HSV
- an STI patient is not considered treated until the management of his/her partner(s) is ensured (contact tracing by Public Health)
- patients diagnosed with bacterial STI or trichomonal infection should abstain from sexual activity until treatment completion and for 7 d after treatment for both partners, or until test of cure completed
- mandatory reporting: chlamydia, gonorrhea, hepatitis B, HIV, syphilis

Efficacy of Human Papillomavirus Vaccines – A Systematic Quantitative Review
Int J Gynecol Cancer 2009;19:1166-1176

Purpose: To evaluate two vaccines for human papillomavirus (HPV) in terms of efficacy, safety and immunogenicity.

Methods: Systematic review of RCTs involving women between the ages of 9 and 26 yr, randomly assigned to receive vaccination with HPV L1 virus-like particle in either quadrivalent (HPV 6, 11, 16, 18), bivalent (HPV 16, 18), or univalent (HPV 16) form or placebo. Main outcomes were prevention of cytologically and/or histologically proven lesions (including LSIL, HSIL, VIN, VAIN, AIN, adenocarcinoma in situ of the cervix, or cancer of the cervix associated with HPV infection).

Results: Six studies involving 47,236 women were included. Bivalent and quadrivalent vaccines reduced the rate of lesions in the cervix, vulva, vagina, and anogenital region with efficacy of 93% (95% CI 87-96%) and 62% (95% CI 27-70), respectively. More symptoms were found in the bivalent vaccine group (50%, 5-73%) compared to control groups.

Conclusion: Prophylactic vaccination can prevent HPV infection in women aged 9 to 26 yr not previously infected with HPV subtypes covered by the vaccines.
**Table 22. Diagnosis and Treatment of Common STIs**

</tr>
</tbody>
</table>

*F = females; M = males

*NB. If urethritis/cervicitis is suspected, always treat for both gonococcal and non-gonococcal types (i.e. ceftriaxone AND azithromycin)

**Most common reportable STI in Canada

---

**Sinusitis**

- see Otolaryngology, OT24

**Etiology**

- viral etiology is more common
- viral: rhinovirus, influenza, parainfluenza
- bacterial: *S. pneumoniae, H. influenzae, M. catarrhalis*

**Management of Acute Sinusitis**

- for symptom relief: oral analgesics (acetaminophen, NSAIDs), nasal saline rinse, short-term use of topical/ or oral decongestants
- do not prescribe antihistamines
- mild to moderate acute bacterial sinusitis: intra-nasal corticosteroids
- severe acute bacterial sinusitis: antibiotics and intra-nasal corticosteroids
- first-line antibiotic is amoxicillin, and second line is amoxicillin-clavulanic acid or a fluoroquinolone
- ENT referral if: anatomic defect (e.g. deviated septum, polyp, adenoid hypertrophy), failure of second-line therapy, or ≥2 episodes/yr, refer urgently when there is development of complications (e.g. orbital extension, meningitis, intra-cranial abscess, venous sinus thrombosis), altered mental status, headache, systemic toxicity, or neurological findings

- **Red Flags for Urgent Referral**

  - Altered mental status
  - Headache
  - Systemic toxicity
  - Swelling of the orbit or change in visual acuity or extraocular muscles
  - Hard neurological findings
  - Signs of meningeal irritation
  - Suspected intra-cranial complications (meningitis, intra-cranial abscess, cavernous sinus thrombosis)
  - Involvement of associated structures (periorbital cellulitis, Pott’s puffy tumour)
Common Presenting Problems

Figure 16. Diagnosis and management of sinusitis

Sleep Disorders

- see Respirology, R28 and Neurology, N46

Definition
- most often characterized by one of three complaints
  - insomnia
  - difficulty falling asleep, difficulty maintaining sleep, early morning wakening, non-refreshing sleep
  - parasomnias
  - night terrors, nightmares, restless leg syndrome, somnambulism (performing complex behaviour during sleep with eyes open but without memory of event)
  - excessive daytime sleepiness

Epidemiology
- 1/3 of patients in primary care setting have occasional sleep problems, 10% have chronic sleep problems

Etiology
- primary sleep disorders
  - primary insomnia, narcolepsy, obstructive sleep apnea, restless leg syndrome, periodic limb movements of sleep
- secondary causes
  - medical: COPD, asthma, CHF, hyperthyroidism, chronic pain, BPH, menopause, GERD, PUD, pregnancy, neurological disorders
Common Presenting Problems

Investigations
- complete sleep diary every morning for 1-2 wk
  - record bedtime, sleep latency, total sleep time, awakenings, quality of sleep
- rule out specific medical problems (e.g. CBC and differential, TSH)
- refer for sleep study, nocturnal polysomnogram, or daytime multiple sleep latency test if suspicion of sleep apnea or periodic leg movements of sleep

Management of Specific Problems

Primary Insomnia
- person reacts to insomnia with fear or anxiety around bedtime or with a change in sleep hygiene, which can progress to a chronic disorder (psychophysiological insomnia)
- treat any suspected medical or psychiatric cause
- exercise regularly, avoid heavy exercise within 3 h of bedtime
- first-line treatment (CBT)
  - sleep hygiene: avoid alcohol, caffeine, nicotine; comfortable sleep environment; regular sleep schedule; no napping
  - relaxation therapy: deep breathing, meditation, biofeedback
  - stimulus control therapy: re-association of bed/bedroom with sleep, re-establishment of a consistent sleep-wake schedule, reduce activities that cue staying awake
  - sleep restriction therapy: total time in bed should closely match the total sleep time of the patient
  - address inappropriate beliefs and attitudes that perpetuate dysfunctional sleep
- pharmacologic treatment (used to supplement CBT; short-term prescription of <14 d with appropriate follow-up in 7-14 d):
  - short-acting benzodiazepines (e.g. lorazepam) are used to:
    - break the cycle of chronic insomnia
    - manage an exacerbation of previously controlled insomnia
  - non-benzodiazepines: zopiclone, zolpidem, melatonin, sedating anti-depressants (e.g. amitriptyline, trazadone)
  - if no progress or limited improvement on pharmacotherapy, consider referral to sleep medicine program
- other treatment: exercise regularly, avoid heavy exercise within 3 h of bedtime

Snoring
- results from soft tissue vibration at the back of the nose and throat due to turbulent airflow through narrowed air passages
- physical exam: obesity, nasal polyps, septal deviation, hypertrophy of the nasal turbinates, enlarged uvula and tonsils
- investigations (only if severely symptomatic): nocturnal polysomnography and airway assessment (CT/MRI)
- treatment
  - sleep on side (position therapy), weight loss
  - nasal dilators, tongue-retaining devices, mandibular advancement devices
  - at risk of developing obstructive sleep apnea

Obstructive Sleep Apnea (OSA)
- apnea (no breathing for ≥10 s) resulting from partial or complete upper airway obstruction due to collapse of the base of the tongue, soft palate with uvula, and epiglottis; respiratory effort is present
- leads to a distinctive snorting, choking, awakening type pattern as the body rouses itself to open the airway
- apneic episodes can last from 20 s-3 min and occur 100-600 episodes/night
- diagnosis is based on nocturnal polysomnography: >15 apneic/hypopneic episodes per hour of sleep
- consequences
  - daytime somnolence, non-restorative sleep
  - poor social and work performance
  - mood changes: anxiety, irritability, depression
  - sexual dysfunction: poor libido, impotence
  - morning headache (due to hypercapnia)
  - HTN (2x increased risk), CAD (3x increased risk), stroke (4x increased risk), arrhythmias
  - OSA is an independent risk factor for CAD
  - pulmonary HTN, right ventricular dysfunction, cor pulmonale (due to chronic hypoxemia)
  - memory loss, decreased concentration, confusion
- investigations
  - evaluate BP, inspect nose, and oropharynx (enlarged adenoids or tonsils)
  - blood gas not helpful, TSH if clinically indicated
  - nocturnal polysomnography
- treatment
  - modifiable factors: avoid sleeping supine; weight loss; avoid alcohol, sedatives, opioids; inhaled steroids if nasal swelling present; dental appliances to modify mandibular position
  - primary treatment of OSA is CPAP: maintains patent airway in 95% of OSA cases
  - surgery: somnoplasty, uvulopalatopharyngoplasty (UPPP), tonsillectomy, and adenoidectomy (in children)
  - report patient to Ministry of Transportation if OSA is not controlled by CPAP

Risk Factors for Obstructive Sleep Apnea
- 2% of women, 4% of men between ages 30-60
- Obesity (due to upper airway narrowing). BMI >28 kg/m² present in 60-90% of cases
- Children (commonly due to large tonsils and adenoids)
- Aging (due to decreased muscle tone)
- Persistent URTIs, allergies, nasal tumors, hypothyroidism (due to macroglossia), neuromuscular disease
- Family history
Sore Throat (Pharyngitis)

**Definition**
- inflammation of the oropharynx
- may be caused by a wide range of infectious organisms, most of which produce a self-limited infection with no significant sequelae

**Etiology**
- viral: adenovirus, rhinovirus, influenza virus, RSV, EBV, coxsackie virus, herpes simplex virus, CMV, HIV
- bacterial: Group A β-Hemolytic Streptococcus (GABHS), Group C and Group β-Hemolytic Streptococcus, Neisseria gonorrhoeae, Chlamydia pneumoniae, Mycoplasma pneumoniae, Corynebacterium diphteritae

**Epidemiology**
- viral
  - most common cause (90% in adults is viral), occurs year round
- bacterial
  - GABHS (Group A β-Hemolytic Streptococcal Infections)
    - most common bacterial cause
    - occurs most often in winter months
    - 5-15% of adult cases and up to 50% of all pediatric cases of acute pharyngitis
    - most prevalent between 5-17 yr old

**Clinical Features**
- viral
  - pharyngitis, conjunctivitis, rhinorrhea, hoarseness, cough
  - nonspecific flu-like symptoms such as fever, malaise, and myalgia
  - often mimics bacterial infection
  - common viral infections
    - EBV (infectious mononucleosis)
    - pharyngitis, tonsillar exudate, fever, lymphadenopathy, fatigue, rash
    - coxsackie virus (hand, foot, and mouth disease)
      - primarily late summer, early fall
      - sudden onset of fever, pharyngitis, headache, abdominal pain, and vomiting
      - appearance of small vesicles that rupture and ulcerate on soft palate, tonsils, pharynx
      - ulcers are pale grey and several mm in diameter, have surrounding erythema, and may appear on hands and feet
    - herpes simplex virus
      - like coxsackie virus but ulcers are fewer and larger
      - pharyngitis, tonsillar exudate, fever, lymphadenopathy, fatigue, rash
- bacterial
  - symptoms: pharyngitis, fever, malaise, headache, abdominal pain, absence of cough
  - signs: fever, tonsillar or pharyngeal erythema/exudate, swollen/tender anterior cervical nodes, halitosis
  - complications:
    - suppurative: abscess, sinusitis, otitis media, cervical adenitis, pneumonia
    - non-suppurative: acute rheumatic fever, acute glomerulonephritis

**Investigations**
- suspected GABHS
  - gold standard is throat culture
  - rapid test for streptococcal antigen: high specificity (95%) but low sensitivity (50-90%)
- suspected EBV (infectious mononucleosis)
- peripheral blood smear, heterophile antibody test (i.e. the latex agglutination assay or “monospot”)

**Table 23. Modified Centor Score: Approach to Diagnosis and Management of GABHS**

*Clinical grounds include a high fever or other indicators that the patient is clinically unwell and is presenting early in the course of the illness
Limitations: *This score is not applicable to patients <3 yr of age
*If an outbreak or epidemic of illness caused by GABHS is occurring in any community, the score is invalid and should not be used

Management
- viral pharyngitis
  - antibiotics not indicated
  - symptomatic therapy: acetaminophen/NSAIDs for fever and muscle aches, decongestants
- GABHS
  - antibiotic treatment decreases severity and duration of symptoms, risk of transmission (after 24 h of treatment), and risk of rheumatic fever and suppurative complications
  - 10 d of treatment required
  - incidence of glomerulonephritis is not decreased with antibiotic treatment
  - no increased incidence of rheumatic fever with 48 h delay in antibiotic treatment; if possible, delay antibiotic treatment until culture confirms diagnosis
  - routine F/U and/or post-treatment throat cultures are not required for most patients
  - F/U throat culture only recommended for: patients with history of rheumatic fever, patients of family member(s) with history of acute rheumatic fever, suspected streptococcal carrier
- infectious mononucleosis (EBV)
  - self-limiting course; antibiotics are not indicated
  - symptomatic treatment: acetaminophen/NSAIDs for fever, pharyngitis, malaise
  - avoid heavy physical activity and contact sports for at least 1 mo or until splenomegaly resolves because of risk of splenic rupture
  - if acute airway obstruction, give corticosteroids and consult ENT

Palliative Care

Principles and Quality of Life
- support, educate, and treat both patient and family
- address physical, psychological, social and spiritual needs
- focus on symptom management and comfort measures
- offer therapeutic environment and bereavement support
- ensure maintenance of human dignity

End-of-Life Care Discussions
When to Initiate End-of-Life Care Discussions
- recent hospitalization for serious illness
- severe progressive medical condition(s)
- death expected within 6-12 mo
- patient request
- medical aid in dying
  - important to discuss grief/bereavement with loved ones

Power of Attorney
- see Ethical, Legal, and Organizational Medicine, ELOM10

Instructional Advance Directives
- see Ethical, Legal, and Organizational Medicine, ELOM10

Symptom Management
Assessment Tools
- Edmonton Symptom Assessment System (ESAS): asks patients to rate intensity of 9 common cancer/palliative symptoms (pain, tiredness, nausea, depression, anxiety, drowsiness, appetite, well-being, shortness of breath, “other”) and monitor over time
- Palliative Performance Scale (PPS): assesses 5 functional components (ambulation, activity and evidence of disease, self-care, intake, conscious level) to predict survival in terminally-ill patients
  - PPS scores are determined by reading from left to right at each PPS level until the level that best fits the patient's functional status is found
  - PPS <30% indicative of <3 mo prognosis

Guidance on the Management of Pain in Older People
Age Aging 2013; 42:1-57
The three most common sites of pain in older adults are the back, leg/knee and hip. Acetaminophen should be considered first-line treatment for the management of both acute and persistent pain, particularly that which is of musculoskeletal origin. NSAIDs should be prescribed with caution and co-prescribed with a PPI.

Epidemiology
- 50-75% of Canadians report some use of CAM over their lifetime, and only half will disclose this use to their physician
- use is highest in Western provinces and lowest in Atlantic provinces
- more likely to be used by younger patients and those with higher education and income
- examples: chiropractic, acupuncture, massage, naturopathy, homeopathy, traditional Chinese medicine, craniosacral therapy, osteopathy

Herbal Products
- over 50% of Canadians use natural health products (NHPs)
- most commonly used include echinacea, ginseng, ginkgo, garlic, St. John's wort, and soy
- relatively few herbal products have been shown to be effective in clinical trials
- many patients believe herbal products are inherently safe and are unaware of potential side effects and interactions with conventional medicines
- all NHPs must be regulated under The Natural Health Products Regulations as of January 1, 2004, including herbal remedies, homeopathic medicines, vitamins, minerals, traditional medicines, probiotics, amino acids, and essential fatty acids (e.g. omega-3)
- always ask patients whether they are taking any herbal product, herbal supplement, or other natural remedy. Further questions may include:
  - Are you taking any prescription or non-prescription medications for the same purpose as the herbal product?
  - Are you allergic to any plant products?
  - Are you pregnant or breastfeeding?
- information resources: National Centre for CAM (www.nccam.nih.gov), Health Canada website

<tr>
<td><strong>Pharyngitis</strong> (sore throat)</td>
<td>Rhinovirus, adenovirus, influenza, parainfluenza, coxsackie virus, coronavirus</td>
<td>None</td>
</tr>
</tbody>
</table>
| **Strep Pharyngitis** | Group A β-Hemolytic Streptococcus | Children:  
1st line: penicillin V 40 mg/kg/d PO div bid-tid (max 750 mg/d) x 10 d (use adult dose if >27 kg) amoxicillin 40 mg/kg/d PO div bid-tid x 10 d  
2nd line: erythromycin estolate 40 mg/kg/d PO div bid-tid x 10 d  
3rd line: cefprozil 15 mg/kg/d PO div bid x 10 d  
Adults:  
1st line: penicillin V 300 mg PO tid or 600 mg bid x 10 d amoxicillin 40 mg/kg/d PO div bid-tid x 10 d  
2nd line: erythromycin 250 mg PO qid x 10 d  
3rd line: cephalaxin 500 mg PO qid x 10 d |
| **Sinusitis** | S. pneumoniae H. influenzae M. catarrhalis S. aureus | Children:  
1st line: amoxicillin 80 mg/kg/d PO div bid-tid (max 3 g/d) x 5-10 d  
2nd line: amoxicillin/clavulanate 40-80 mg/kg/d PO div bid (max 3 g/d) x 10-14 d  
3rd line: cefprozil 30 mg/kg/d PO div bid x 10-14 d  
3rd line: cefuroxime-AX 30-40 mg/kg/d PO div bid x 10-14 d  
3rd line: clarithromycin 15 mg/kg/d PO div bid x 10-14 d  
Adults:  
1st line: amoxicillin 500 mg PO tid x 5-10 d  
2nd line: amoxicillin/clavulanate 500 or 875 mg PO bid x 5-10 d  
3rd line: cefuroxime-AX 250-500 mg PO bid x 5-10 d |
| **Acute Otitis Media** | S. pneumoniae H. influenzae M. catarrhalis Group A Strep S. aureus | Treat if under age 6 mo  
If age 6-24 mo, watchful waiting appropriate if parents can observe child for 48-72 h with appropriate medical follow-up  
If age >24 mo, treat if worsens after 48-72 h  
10 d course if age <6mo, 5 d course if age >6mo  
1st line: amoxicillin 80 mg/kg/d PO div bid-tid (max 3 g/d)  
2nd line: amoxicillin/clavulanate 40-80 mg/kg/d PO div bid (max 3 g/d)  
3rd line: cefuroxime-AX 30-40 mg/kg/d PO div bid  
3rd line: clarithromycin 15 mg/kg/d PO div bid  
Chronic TM perforation or ventilation tubes: Ciprodex® otic suspension 4 drops bid x 5 d  
Adults:  
1st line: amoxicillin 500 mg PO tid x 7-10 d  
2nd line: amoxicillin/clavulanate 500 mg PO tid or 875 mg PO bid x 7-10 d  
3rd line: cefuroxime-AX 250-500 mg PO bid x 7-10 d  
Chronic TM perforation or ventilation tubes: Ciprodex® otic suspension 4 drops bid x 5 d |
| **Otitis Externa** | P. aeruginosa Califorms S. aureus | Cortisporin® otic solution 4 drops tid or qid (3 drops tid or qid for children)  
TM defect: Ciprodex® otic suspension 4 drops bid x 5 d  
Necrotizing (i.e. bone involvement): ciprofloxacin 750 mg PO bid x 4-8 wk |
| **Bronchitis** | H. influenzae, parainfluenza, coronavirus, rhinovirus, RSV | None |
| **Community Acquired Pneumonia: Outpatient without Comorbidity** | S. pneumoniae M. pneumoniae C. pneumoniae | 1st line: amoxicillin 1000 mg PO tid x 7-14 d  
for patients over age 50 where mycoplasma infection is less likely  
erythromycin 500 mg PO qid x 7-14 d  
clarithromycin 500 mg PO bid or 1000 mg (ER) PO OD x 7-14 d  
azithromycin 500 mg PO on 1st d then 250 mg PO OD x 4 d or 500 mg PO OD x 3 d  
2nd line: doxycycline 100 mg PO on 1st d then 100 mg PO OD x 7-14 d  
PLUS ONE of the following:  
clarithromycin 500 mg PO bid or 1000 mg (ER) PO OD x 7-14 d  
azithromycin 500 mg PO OD on 1st d then 250 mg PO OD x 4 d or 500 mg PO OD x 3 d  
doxycycline 100 mg PO on 1st d then 100 mg PO OD x 7-14 d  
OR ANY ONE of the following:  
levofloxacin 750 mg PO OD x 7-14 d  
moxifloxacin 400 mg PO OD x 7-14 d |
| **Community Acquired Pneumonia: Outpatient with Comorbidity** | S. pneumoniae M. pneumoniae C. pneumoniae H. influenzae | ANYONE of the β-lactam agents below:  
amoxicillin 1000 mg PO tid x 7-14 d  
amoxicillin/clavulanate 500 mg PO tid or 875 mg PO bid x 7-14 d  
cefuroxime-AX 500 mg PO bid x 7-14 d  
cefprozil 500 mg PO bid x 7-14 d  
PLUS ONE of the following:  
clarithromycin 500 mg PO bid or 1000 mg (ER) PO OD x 7-14 d  
azithromycin 500 mg PO OD on 1st d then 250 mg PO OD x 4 d or 500 mg PO OD x 3 d  
doxycycline 100 mg PO on 1st d then 100 mg PO OD x 7-14 d |
| **Dental Infections/Periapical and Periodontal Abscesses** | Oral Flora | penicillin V potassium 500 mg PO qid x 7-10 d  
clindamycin 300 mg PO qid or 600 mg bid x 7-10 d |
### Gastroenterology

#### Diarrhea – Enteritis

<table>
<thead>
<tr>
<th>Condition Microorganisms</th>
<th>Antimicrobial</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enterotoxigenic <em>E. coli</em> (ETEC)</td>
<td>Mild to moderate (i.e. &lt;3 bowel movements per day, no blood, no fever): OTC loperamide 4 mg PO STAT then 2 mg PO after each loose stool (max 8 doses/d) OTC bismuth subsalicylate (Pepto Bismol®) 2 tabs or 30 mL repeat q30min pm (max 8 doses/d) (prevention: 2 tabs or 30 mL qid with meals and in the evening)</td>
</tr>
</tbody>
</table>

| Moderate to severe (i.e. >3 BM/d, blood, fever): | |
| ciprofloxacin 750 mg PO single dose or 500 mg PO bid x 1-3 d (prevention: 500 mg PO OD) | |
| levofloxacin 500 mg PO OD x 1-3 d (prevention: 500 mg PO OD) | |
| azithromycin 1000 mg PO single dose or 500 mg PO OD x 1-3 d (children: 10 mg/kg/d x 3 d) | |

| Azithromycin: | |
| Recommended primarily for Thailand, India, Nepal, and Indonesia where Campylobacter resistance to quinolones is high |
| Considered drug of choice for children because of safety, tolerability, and ease of administration |

#### Diarrhea – Post Antibiotics

<table>
<thead>
<tr>
<th>Condition Microorganisms</th>
<th>Antimicrobial</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>C. difficile</em></td>
<td>Mild to moderate (WBC &lt;5 x 10⁹/L and Cr &lt;1.5 x baseline): metronidazole 500 mg PO tid or 250 mg PO qid x 10 d (children: 15-30 mg/kg/d PO div tid-qid max 4 g/d)</td>
</tr>
</tbody>
</table>

| Severe (WBC ≥15 x 10⁹/L and Cr ≥1.5 x baseline): | |
| vancomycin 125 mg PO qid x 10-14 d (children: 40 mg/kg/d PO div tid-qid x 10-14 d max 2 g/d) | |

#### Peptic Ulcer Disease

</table>
Visualizing the Gastrointestinal Tract

- see Medical Imaging, MI16

Esophagus, Stomach, Duodenum
- OGD: best visualization of mucosa; also allows for therapeutic intervention (e.g. banding varices, thermal therapy/clipping/injecting bleeding ulcers, and dilatation e.g. treatment of esophageal strictures)
  - consider barium swallow first if dysphagia, decreased level of consciousness (increases risk of aspiration), inability to cooperate (increases risk of pharyngeal trauma during intubation), possibility of fistulas
  - endotracheal intubation first if massive upper GI bleed, acidemia, or inability to protect airway

Small Bowel
- most difficult to visualize, especially if mucosal detail is needed
- CT enterography more accurate than small bowel follow through, but both have low sensitivity
- MRI small bowel imaging increasingly available, especially useful if radiation exposure is an issue (e.g. young patient, multiple radiological images already done)
  - note: MRI enteroclysis: luminal contrast administered by nasojejunal tube to dilate the small bowel – disliked by both radiologist and patient, but may improve sensitivity
- “double balloon” enteroscopy (enteroscope with proximal and distal balloons to propel endoscope into jejunum from mouth or into jejunum/ileum or into ileum from anus) may be most sensitive but currently available only in selected centres; technically demanding
- wireless endoscopy capsule (26 x 11 mm capsule is swallowed, transmits images to a computer; contraindicated in bowel obstruction) is also accurate in diagnosis but unable to provide any therapeutic intervention

Colon and Terminal Ileum
- colonoscopy, with biopsy if required; contraindicated in perforation, acute diverticulitis, and severe colitis (increased risk of perforation)
- CT colonography (“virtual colonoscopy”) more accurate in diagnosing diverticulosis, extrinsic pressure on colon (e.g. ovarian cancer compressing sigmoid colon), and fistula; increasing evidence for use in colorectal cancer screening, especially for assessment of right side of colon in cases where colonoscopy is less sensitive
  - most often used when optical endoscopic colonoscopy is a risk (e.g. frail elderly) or unsuccessful (e.g. stricture)

Pancreatic/Biliary Duct
- MRCP almost as sensitive as ERCP in determining if bile duct obstruction present, but less accurate in determining cause of obstruction (tumour, stone, stricture)
- ERCP if therapeutic intervention likely to be required: strong suspicion of stone, obstruction requiring stenting, or if tissue sampling required
- Endoscopic ultrasound can provide detailed anatomy of biliary tree and pancreas with potential for sampling/intervention (cyst drainage)

Differential Diagnosis of Common Complaints

Inflammatory Diarrhea: Occurs when there is damage to the mucosal lining or brush border, which leads to a passive loss of protein-rich fluids and a decreased ability to absorb these lost fluids. Diarrhea may be profuse or very small in volume. Often associated with abdominal pain ± fever and chills.

Non-Inflammatory Diarrhea: No damage to the mucosal lining. Nausea/vomiting may be present. Fever, chills, blood in the stool, severe abdominal pain or tenderness are not present.

**Constitution:** if no associated rectal bleeding/weight loss, usually no cause found (and dysmotility assumed)

**Lower GI bleed:**
- **Common:** Diverticulitis, Ischemia, Angiodysplasia (elderly), Infectious, Anorectal (hemorrhoids, fissure, ulcer)
- **Uncommon:** Upper GI bleed (brisk), Post-polypectomy, Radiation colitis, IBD
- **Rare:** Intussusception, Vasculitides, Stercoral ulcer, Coagulopathies

**Upper GI bleed:**
- **Common:** Ulcers (BA, Pylor, ASA, NSAIDs), Esophageal varices, Mallory-Weiss tears, Erosive esophagitis, Erosive gastritis
- **Uncommon:** Tumours, Arteriovenous malformation, Bleomycin's lesion (arterial), Gastric antral vascular ectasia (GAVE)
- **Rare:** Anal enteritis, Hemorrhoids, Hemobilia

**Dysphagia:**
- **Mechanical (Solids):** Peptic stricture/cancer, Eosinophilic esophagitis, Extrinsic compression, Schatzki rings/esophageal web, Zenker's diverticulum
- **Motility (Solids and Liquids):** Achalasia, Diffuse esophageal spasm, Scleroderma
- **Other:** Foreign body, Eosinophilic esophagitis

**Odynophagia:**
- **Infection:** Candida, Herpes, CMV (common in those who are immunosuppressed)
- **Inflammation/Ulceration:** Caustic damage, Eosinophilic esophagitis
- **Drugs:** Quinidine, Iron, Vitamin C, Antibiotics (e.g. tetracycline), Bisphosphonates
- **Other:** Radiation

**Abdominal distention:**
- **Normal Portal Pressure:** Portal HTN, Cirrhosis, Cardiac failure, Hepatic vein thrombosis
- **Portal HTN:** Cancer, (especially ovarian), Pancreatitis, TB
- **Constitution:** Functional bowel disease (e.g. IBS), Fibre
- **Constipation:** Colon obstruction, Dysmotility
- **Pregnancy (fetus):** Obesity (fat, Blood, Largeness (fetal growth)

**Commonly Forgotten Causes of Vomiting:**
- **6 Fs:** Marijuana, Uremia, CNS Disease, Pregnancy, Marijuana, Cannabinoid hyperemesis

**Difference Between Dysphagia and Odynophagia:**
- **Dysphagia:** Difficulty swallowing due to mechanical obstruction or dysmotility of the esophagus or pharynx.
- **Odynophagia:** Pain when swallowing due to ulceration or inflammation (e.g., eosinophilic esophagitis) in the esophagus or pharynx.

**Differential Diagnosis of Abdominal Distention:**
- **6 Fs:** Fat, Feces, Fetus, Ruptus, Fluid, Fetal Growth

Gastroesophageal Reflux Disease

Definition
- a condition which develops when the reflux of gastric content causes troublesome symptoms or complications

Etiology
- inappropriate transient relaxations of LES – most common cause
- low basal LES tone (especially in scleroderma)
- contributing factors include: delayed esophageal clearance, delayed gastric emptying, obesity, pregnancy, acid hypersecretion (rare) from Zollinger-Ellison syndrome (gastrin-secreting tumour)
- hiatus hernia worsens reflux, does not cause it (see General Surgery, GS13)

Clinical Features
- “heartburn” (pyrosis) and regurgitation (together are 80% sensitive and specific for reflux); less sensitive and less specific: water brash, sensation of a lump in the throat (globus sensation), and frequent belching
  - non-esophageal symptoms are increasingly recognized of being poor predictors of reflux

Investigations
- usually, a clinical diagnosis is sufficient based on symptom history and relief following a trial of pharmacotherapy (PPI: symptom relief 80% sensitive for reflux)
- however, response to anti-secretory agents such as PPI is not a requirement for GERD diagnosis
  - absolute indications
    - heartburn accompanied by red-flags (bleeding, weight loss, dysphagia, persisting vomiting, family history of GI cancer etc.)
    - persistent reflux symptoms or prior severe erosive esophagitis after therapeutic trial of 4-8 wk of PPI 2x daily
    - history suggests esophageal stricture especially dysphagia
    - high risk for Barrett’s (male, age >50, obese, white, tobacco use, long history of symptoms)
- repeat endoscopy after 6-8 wk of PPI therapy indicated if: severe esophagitis because it can mask Barrett’s esophagus or symptoms

Figure 2. Signs and symptoms of GERD

GERD signs/symptoms
- Non-esophageal
  - Respiratory
    - Chronic cough
    - Wheezing
    - Aspiration pneumonia
  - Non-respiratory
    - Sore throat
    - Hoarseness
    - Dental erosions
- Esophageal
  - Typical
    - Heartburn
    - Acid regurgitation
  - Atypical
    - Chest pain
    - Dysphagia (late)
    - Odynophagia (rare)

Figure 3. Classification and gastroscopic findings of GERD

Gastroesophageal Reflux Disease

Dyspepsia = postprandial fullness, early satiety, epigastric pain, or burning

Foods/Substances that may aggravate GERD Symptoms (but diet does not change the underlying disease)
- EtOH
- Caffeine
- Tobacco
- Fatty/fried foods
- Chocolate
- Peppermint
- Spicy foods
- Citrus fruit juices

Bowel Ischemia
The splenic flexure and rectosigmoid junction are watershed areas and are susceptible to ischemia. History and symptoms include acute onset crampy left abdominal pain, absence of abdominal tenderness on exam, rectal bleeding, and risk factors for embolization, atherosclerosis and atrial fibrillation
Esophageal manometry (study of esophageal motility): indicated in patients who have a normal gastroscopy but with chest pain and/or dysphagia
- done to diagnose abnormal peristalsis and/or decreased LES tone, but cannot detect presence of reflux; indicated before surgical fundoplication to ensure intact esophageal function; exclude alternative diagnoses like scleroderma and achalasia
- surgical fundoplication (wrapping of gastric fundus around the lower end of the esophagus) more likely to alleviate symptoms if low esophageal pressure is diminished; less likely to be successful if abnormal peristalsis
- 24 h pH monitoring: most accurate test for reflux, but not required or performed in most cases
- most useful if PPIs do not improve symptoms

Treatment
- PPIs are the most effective therapy and usually need to be continued as maintenance therapy
- on-demand: antacids (Mg(OH)_2, Al(OH)_3, alginate), H2-blockers, or PPIs can be used for NERD
- diet helps symptoms, not the disease; avoid alcohol, coffee, spices, tomatoes, and citrus juices
- only beneficial lifestyle changes are weight loss (if obese) and elevating the head of bed (if nocturnal symptoms)
- symptoms may recur if therapy is discontinued

Complications
- esophageal stricture disease – scarring can lead to dysphagia (solids)
- esophagitis
- ulcer
- bleeding
- Barrett’s esophagus and esophageal adenocarcinoma – gastroscopy is recommended for patients with chronic GERD or symptoms suggestive of complicated disease (e.g. anorexia, weight loss, bleeding, dysphagia)

Barrett’s Esophagus

Definition
- metaplasia of normal squamous esophageal epithelium to intestinal columnar epithelium containing-type intestinal mucosa (intestinal metaplasia)

Etiology
- thought to be acquired via long-standing GERD and consequent damage to squamous epithelium

Epidemiology
- in North America and Western Europe, 0.5-20% of adults are thought to have Barrett’s esophagus
- up to 10% of GERD patients will have already developed BE by the time they seek medical attention
- more common in males, age >50, Caucasians, smokers, overweight, hiatus hernia, and long history of reflux symptoms

Pathophysiology
- endoscopy shows erythematous epithelium in distal esophagus; diagnosis of BE relies on biopsy demonstrating the presence of specialized intestinal epithelium of any length within the esophagus
- BE predisposes first to premalignant changes characterized as low or high-grade dysplasia, which then progresses to adenocarcinoma

Significance
- rate of malignant transformation is approximately 0.12% per yr for all BE patients prior to dysplasia
- risk of malignant transformation in high-grade dysplasia is significantly higher; studies have reported a 32-59% transformation rate over 5-8 yr of surveillance
- increased gastric acid secretion is more frequently associated with Barrett’s esophagus as opposed to reflux alone

Treatment
- acid suppressive therapy with high-dose PPI indefinitely (or surgical fundoplication
- surveillance gastroscopy every 3 yr if no dysplasia
- high grade dysplasia: regular and frequent surveillance with intensive biopsy, endoscopic ablation/resection, or esophagectomy produce similar outcomes; however, evidence increasingly favouring endoscopic ablation with mucosal resection or radiofrequency ablation
- if low grade dysplasia, both surveillance (every 6 mo for 1 yr then annually) and endoscopic ablation/resection are satisfactory options
Dysphagia

Definition
- difficulty swallowing

Clinical Features
- dysphagia with solids and liquids
- chest pain (in some disorders)

Diagnosis
- motility study (esophageal manometry)
- barium swallow sometimes helpful

Causes
- idiopathic
- achalasia
- scleroderma
- DM
- DES: rare and can be difficult to diagnose due to intermittent presentation

Table 3. Esophageal Motor Disorder

<table>
<thead>
<tr>
<th>Disorder</th>
<th>Achalasia</th>
<th>Scleroderma</th>
<th>Diffuse Esophageal Spasm</th>
</tr>
</thead>
<tbody>
<tr>
<td>Definition</td>
<td>Failure of smooth muscle relaxation at LES</td>
<td>Systemic disease characterized by vasculopathy and tissue fibrosis (especially skin thickening)</td>
<td>Normal peristalsis interspersed with frequent, repetitive, spontaneous, high pressure, non-peristaltic waves (tertiary peristalsis)</td>
</tr>
<tr>
<td>Etiology</td>
<td>Usually idiopathic</td>
<td>Involves autoimmune, genetic, hormonal, and environmental factors</td>
<td>Idiopathic</td>
</tr>
<tr>
<td>Pathophysiology</td>
<td>Inflammatory degeneration of Auerbach’s plexus → increase in LES pressure, incomplete relaxation of LES with swallowing, aperistalsis</td>
<td>Blood-vessel damage → intramural neuronal dysfunction → distal esophageal muscle weakening → aperistalsis and loss of LES tone → reflux → stricture → dysphagia</td>
<td>Potential mechanisms include impaired inhibitory innervation to esophageal body, malfunction in endogenous nitric oxide synthesis</td>
</tr>
<tr>
<td>Diagnosis</td>
<td>CXR: no air in stomach, dilated esophagus Barium studies: esophagus terminates in narrowing at LES (“bird’s beak”) Endoscopy: normal mucosa Manometry: definitive diagnosis (signs listed above)</td>
<td>Clinical features of scleroderma: Manometry: decreased pressure in LES, decreased peristalsis in body of esophagus</td>
<td>Barium x-ray: “Corkscrew pattern” Manometry: &gt;30% (but &lt;100%) of esophageal contractions are aperistaltic Endoscopy: normal mucosa</td>
</tr>
<tr>
<td>Treatment</td>
<td>Dilation of LES with balloon, pH GERD prophylaxis, 50% good response, can repeat, risk of perforation (5%) Injection of botulinum toxin into LES (temporarily) POEM (peroral endoscopic myotomy)</td>
<td>Medical: aggressive GERD therapy, PPIs bid, surgery: anti-reflux surgery (gastroplasty, last resort)</td>
<td>Reassurance not cardiac pain Medical: nitrates, calcium channel blockers, anticholinergics have variable benefit Surgical: long esophageal myotomy, if unresponsive to above treatment (rarely helpful); balloon dilatation</td>
</tr>
</tbody>
</table>
Esophageal Diverticula

**Definition**
- outpouchings of one or more layers of the esophageal tract

**Clinical Features**
- commonly associated with motility disorders
- dysphagia, regurgitation, retrosternal pain, intermittent vomiting, may be asymptomatic

**Classification**
- pharyngoesophageal (Zenker’s) diverticulum
  - most frequent form of esophageal diverticulum
  - posterior pharyngeal outpouching most often on the left side, above cricopharyngeal muscle and below the inferior pharyngeal constrictor muscle
  - symptoms: dysphagia, regurgitation of undigested food, halitosis (bad breath)
  - treatment: small and asymptomatic: no treatment required, large and symptomatic: endoscopic or surgical myotomy of cricopharyngeal muscle ± surgical excision of sac

Peptic Stricture (from Esophagitis)

- presents as dysphagia alongside a long history of reflux symptoms, but reflux symptoms may disappear as stricture develops
- diagnosed with endoscopy or barium study if endoscopy contraindicated or unavailable

**Treatment**
- endoscopic dilatation and indefinite PPI

Esophageal Carcinoma

- see General Surgery, GS15

Webs and Rings

- web = partial occlusion (upper esophagus)
- ring = circumferential narrowing (lower esophagus)

**Clinical Features**
- asymptomatic with lumen diameter >12 mm, provided peristalsis is normal
- dysphagia with large food boluses
- Schatzki ring
  - mucosal ring at squamo-columnar junction
  - causes intermittent dysphagia with solids
  - treatment involves disrupting ring with endoscopic dilation

Infectious Esophagitis

**Definition**
- severe mucosal inflammation and ulceration as a result of a viral or a fungal infection

**Risk Factors**
- DM
- chemotherapeutic agents
- immunocompromised states

**Clinical Features**
- characteristically odynophagia, less often dysphagia

**Appearance**
- Candida (most common): whitish-yellow plaques without visible ulceration or inflammation
- Herpes (second most common), CMV: focal ulcers

**Investigations**
- diagnosis via endoscopic visualization and biopsy

**Treatment**
- Candida: nystatin swish and swallow, ketoconazole, fluconazole
- Herpes: often self-limiting: acyclovir, valacyclovir, famciclovir
- CMV: IV ganciclovir, famciclovir, or oral valganciclovir
Stomach and Duodenum

Dyspepsia

Definition
- predominant epigastric pain/burning lasting at least 1 mo (predominant associated symptoms are vomiting, weight loss, etc. Differential diagnosis revolves around these more ominous symptoms)
- other symptoms under umbrella of dyspepsia: post-prandial fullness, early satiation
- although the most common cause is functional (investigations show no organic disease but pain persists), sinister disease can present similarly (e.g., pancreatic cancer)

History and Physical Exam
- history: most important are age, associated symptoms (such as weight loss and vomiting), and drugs (especially NSAIDs)
- physical exam: adenopathy, abdominal mass/organomegaly, Carnett’s sign (if pain is due to abdominal wall muscle problem then the pain will increase during muscle contraction, such as during a sit-up)

Investigations
- consider blood tests including CBC, liver enzymes, calcium, H. pylori serology, and ultrasound
- gastroscopy to investigate dyspepsia: most causes of dyspepsia are either functional or diagnosable by either blood tests or proton pump inhibitor trial (for peptic disease); however, gastric cancer should not be missed. Consensus guidelines of the Canadian Association of Gastroenterology/American College of Gastroenterology suggest age should be the chief criteria: gastroscopy if age >60 (and if age <60 or under special circumstances such as risk factors for gastric cancer)

Gastritis

Definition
• defined histologically: inflammation of the stomach mucosa

Etiology
• some causative agents may play a role in more than one type of gastritis and an individual patient may have histopathological evidence of more than one type of gastritis

</table>

Clinical Features
• non-erosive gastritis is asymptomatic (except in certain rare causes like Crohn’s disease), does not cause pain; difficult to diagnose clinically or endoscopically – requires biopsy for diagnosis
• erosive gastritis can cause bleeding (pain only if progresses to ulcers – rare); can be seen endoscopically

Treatment
• determined by etiology (see *H. pylori*, G13, NSAID, G13 and Stress-Induced Ulceration, G14)
• non-pharmacological: avoidance of mucosal irritants such as alcohol, NSAIDs, and foods that trigger symptoms

Peptic Ulcer Disease

Definition
• focal defects in the mucosa that penetrate the muscularis mucosal layer; results in scarring (defects superficial to the muscularis mucosa are erosions and do not cause scarring)
• peptic ulcer disease includes defects located in the stomach (gastric ulcers) and duodenum (duodenal ulcers)

Etiology

Table 6. Etiology of Peptic Ulcer Disease

</tbody>
</table>

• NSAID negative, *H. pylori* negative ulcers becoming more commonly recognized
• others: CMV, ischemic, idiopathic
• alcohol: damages gastric mucosa but rarely causes ulcers
• peptic ulcer associated with cigarette smoking, cirrhosis of liver, COPD, and chronic renal failure

Clinical Features
• dyspepsia: most common presenting symptom
  • only 5% of patients with dyspepsia have ulcers, while most have functional disease
  • however, 70% of peptic ulcers are asymptomatic
• may present with complications
  • bleeding 10% (severe if from gastroduodenal artery), perforation 2% (usually anterior ulcers), gastric outlet obstruction 2%
  • posterior inflammation (penetration) 2%; may also cause pancreatitis
• duodenal ulcers: 6 classical features, but history alone cannot distinguish from functional dyspepsia
  • epigastric pain; may localize to tip of xiphoid
  • burning
  • develops 1-3 h after meals
  • relieved by eating and antacids
  • interrupts sleep
  • periodicity (tends to occur in clusters of weeks with subsequent periods of remission)
• gastric ulcers: more atypical symptoms; a biopsy is necessary to exclude malignancy

**Investigations**
- endoscopy (most accurate)
- upper GI series
- H. pylori tests (see Table 7)
- fasting serum gastrin measurement if Zollinger-Ellison syndrome suspected (but most common cause of elevated serum gastrin level is atrophic gastritis)

**Treatment**
- specific management depends on etiology; (see H. pylori, G13, NSAID-Induced Ulceration, G13 and Stress-Induced Ulceration, G14)
- treat H. pylori infection if present; chief advantage of quadruple therapy is to lower recurrence rate of peptic ulcer disease
- stop NSAIDs if possible
- start PPI: inhibits parietal cell H+/K+-ATPase pump which secretes acid
  • heals most ulcers, even if NSAIDs are continued
- other medications (e.g. histamine H2-antagonists) less effective
- discontinue cigarette smoking
- no diet modifications required but some people have fewer symptoms if they avoid caffeine, alcohol, and spices

**Management of Bleeding Peptic Ulcers**
- OGD to explore upper GI tract
- IV pantoprazole continuous drip
- establish risk of rebleeding/continuous bleed (since most ulcers stop bleeding spontaneously)
  • clinical risk factors: increased age (>60), bleeding diathesis, history of PUD, comorbid disease, hemodynamically unstable
  • endoscopic signs of recurrent bleeding (active bleeding, visible vessel, clot, red spot) more predictive than clinical risk factors
  • if ulcer possesses high risk stigmata, then endoscopic therapy should be performed, consider ICU admission

**Suspected Bleeding Peptic Ulcer**
- ABCs: assess vitals (BP and HR, orthostatic changes)
- CBC, lyses, BUN, Cr, INR, blood type, cross and type
- Resuscitate: crystalloids and blood products if indicated

**Endoscopy**
- Active bleeding or visible vessel
- High Risk:
  - Hemostasis: clips, thermal coagulation ± epinephrine injection
  - Continue (or start) IV PPI
- Monitor for re-bleeding in hospital
- If adherent clot: consider removal
- Low Risk:
  - No hemostasis necessary
  - Continue (or start) oral PPI

**Post-Endoscopy**
- Resume clear fluids 6 hours post-endoscopy
- Test for H. pylori
- Counsel re: most likely causes (NSAIDs, anti-platelet agents)
- If re-bleeding: repeat endoscopy with aim of hemostasis
- Consult interventional radiology or surgery if needed

**Figure 6. Approach to management of suspected bleeding peptic ulcer**
Adapted from: Gralnek I, Barkun A, Bantsou M. Management of acute bleeding from a peptic ulcer. NEJM 2008;359:928-937
**H. pylori-Induced Peptic Ulceration**

**Pathophysiology**
- *H. pylori*: Gram-negative flagellated rod that resides within the gastric mucosa, causing persistent infection and inflammation
- acid secreted by parietal cells (stimulated by vagal acetylcholine, gastrin, histamine) necessary for most ulcers
- etiology of peptic ulcer disease secondary to *H. pylori* is not well understood; however, the pattern of colonization correlates with outcome
- gastritis only in antrum (15% of patients), high gastric acid, associated with duodenal ulcer, may progress to gastric metaplasia of duodenum where ulcer forms
- gastritis throughout stomach (“pangastritis” – 85% of patients), low gastric acid, associated with stomach ulcer and cancer

**Epidemiology**
- *H. pylori* is found in about 20% of all Canadians
- highest prevalence in those raised during 1930s
- infection most commonly acquired in childhood, presumably by fecal-oral route
- high prevalence in developing countries, low socioeconomic status (poor sanitation and overcrowding)

**Outcome**
- gastritis (non-erosive) occurs in 100% of patients but is asymptomatic
- peptic ulcer in 15% of patients
- gastric carcinoma and mucosal associated lymphomatous tissue [MALT] lymphoma in 0.5% of patients
- most are asymptomatic but still worthwhile eradicating to lower future risk of peptic ulcer/gastric malignancy and prevent spread to others (mostly children <5 yr of age)

**Diagnosis**

**Treatment: H. pylori Eradication**
- bismuth quadruple therapy recommended for 10-14 d: PPI (e.g. lansoprazole 30 mg bid) + bismuth 525 mg qid + metronidazole 250 mg qid + tetracycline 500 mg qid
- alternatively, concomitant nonbismuth quadruple therapy for 10-14 d: PPI + amoxicillin + metronidazole + clarithromycin

**NSAID-Induced Ulceration**
- NSAID use causes gastric mucosal petechiae in virtually all, erosions in most, ulcers in some (25%)
- erosions bleed, but usually only ulcers cause significant clinical problems
- most NSAID ulcers are clinically asymptomatic; dyspepsia is as common in patients with ulcers as in patients without ulcers; NSAID-induced ulcers characteristically present with complications (bleeding, perforation, obstruction)
- NSAIDs more commonly cause gastric ulcers than duodenal ulcers
- may exacerbate underlying duodenal ulcer disease

**Pathophysiology**
- direct: erosions/petechiae – are due to local (direct) effect of drug on gastric mucosa
- indirect: systemic NSAID effect (intravenous NSAID causes ulcers, but not erosions). NSAIDs also inhibit mucosal cyclooxygenase, leading to decreased prostaglandin synthesis. This results in ulcers from reduced secretion of protective bicarbonate and mucous, and decreased mucosal blood flow
Risk Factors for NSAID-induced Peptic Ulcer
- previous peptic ulcers/upper GI bleed
- age (≥65 yr)
- high dose of NSAID/multiple NSAIDs being taken
- concomitant corticosteroid use
- concomitant cardiovascular disease/other significant diseases

Treatment
- prophylactic cytoprotective therapy with a PPI is recommended if any of the above risk factors exist concomitantly with ASA/NSAID use
- lower NSAID dose or stop all together and replace with acetaminophen
- combine NSAID with PPI or misoprostol (less effective) in one tablet
- enteric coating of Aspirin® (ECASA) provides minor benefit since this decreases incidence of erosion, not incidence of ulceration

Stress-Induced Ulceration

Definition
- ulceration or erosion in the upper GI tract of ill patients, usually in ICU (stress is physiological, not psychiatric)
- lesions most commonly in fundus of stomach

Pathophysiology
- unclear: likely involves ischemia; may be caused by CNS disease, acid hypersecretion, Cushing's ulcers
- mechanical ventilation is the most important risk factor

Risk Factors
- mechanical ventilation
- anti-coagulation
- multi-organ failure
- sepsis
- severe surgery/truma
- CNS injury ("Cushing's ulcers")
- burns involving more than 35% of body surface

Clinical Features
- UGIB (see Upper Gastrointestinal Bleeding, G28)
- painless

Treatment
- prophylaxis with gastric acid suppressants decreases risk of UGIB; PPI most potent but may increase risk of pneumonia; H2 blockers less potent but less likely to cause pneumonia
- treatment same as for bleeding peptic ulcer but often less successful

Gastric Carcinoma
- see General Surgery, GS24

Small and Large Bowel
Classification of Diarrhea

Definition
- clinically: diarrhea defined as stools that are looser and/or more frequent than normal (i.e. ≥3x/d); physiologically: 24 h stool weight >200 g (less useful clinically)

Classification
- acute vs. chronic
- small volume (tablespoons of stool; typical of colonic diseases) vs. large volume (>1/2 cup stool; typical of small bowel diseases)
- watery: secretory (diarrhea persists with fasting) vs. osmotic (diarrhea stops with fasting)
- steatorrhea
- inflammatory
- functional
Acute Diarrhea

**Definition**
- passage of ≥3 loose or liquid stools/d OR >200 g stool/d for >2 d but ≤14 d

**Epidemiology**
- one of the top five leading causes of death worldwide, according to the World Health Organization
- significant morbidity in developed countries (over 900,000 hospitalizations in the United States each year)

**Etiology**
- most commonly due to infections
- most infections are self-limiting and resolve within 7 d

**Risk Factors**
- food (raw or undercooked meat and seafood, unpasteurized dairy products)
- medications: antibiotics, laxatives
- others: high risk sexual activity, infectious outbreaks, occupational exposures (daycare workers), family history (IBD)

**Approach to Acute Diarrhea**
- the vast majority of acute diarrhea is caused by infection
- in most cases, acute diarrheal illness is viral and/or self-limited, and lasts <3 d
- investigations are costly and are necessary only in certain circumstances
  - therefore, evaluation of acute diarrhea involves identifying characteristics of the patient or illness that warrant further investigation and assessing volume status to determine appropriate method of rehydration

**Physical Exam**
- volume status: appearance, level of alertness, pulse, BP, orthostatic vitals, JVP, mucous membranes, skin turgor, capillary refill
- abdominal exam: pain, guarding, peritoneal signs

**Table 8. Classification of Acute Diarrhea**

<table>
<thead>

<tr>
<td>Significance</td>
<td>Higher yield with stool C&amp;S Can progress to life-threatening megacolon, perforation, hemorrhage Antibiotics may benefit</td>
</tr>
</tbody>
</table>

**Investigations**
- stool cultures/microscopy (C&S/O&P) are required only if diarrhea is inflammatory, severe, or for epidemiological purposes (daycare worker, nursing home resident, community outbreaks, e.g. Walkerton, etc.)
  - C&S only tests *Campylobacter, Salmonella, Shigella, E. coli*
  - other organisms must be ordered separately
- flexible sigmoidoscopy (without bowel preparation): useful if inflammatory diarrhea suspected
  - biopsies are the most useful method of distinguishing idiopathic IBD (Crohn's disease and ulcerative colitis) from infectious colitis or acute self-limited colitis
  - *C. difficile* toxin: indicated when recent/remote antibiotic use, hospitalization, nursing home, or recent chemotherapy

**Useful Questions in Acute Diarrhea**

**Infectious Causes of Inflammatory Diarrhea**
- *Yersinia*
- *Shigella*
- *Salmonella*
- *E. coli (EHEC 0157:H7)*
- *E. histolytica*
- *Campylobacter, C. difficile*

**Finally: A Role for Bacteriotherapy**

*Duodenal Infusion of Donor Feces for Recurrent Clostridium difficile*

For centuries, out-of-the-box thinkers have speculated that the colonic bacteria all of us have, but which differs among individuals, play a role in disease. More recently, the colonic microbiome has become the hottest area of research in gastroenterology. The best documented medical indication for manipulating the colonic bacteria is recurrent *C. difficile* infection. In this randomized study of this disease, infusion of donor feces via a nasoduodenal tube resolved diarrhea in 81% of patients, without side-effects, compared to 31% given the standard treatment of oral vancomycin, and 21% of patients given oral vancomycin plus bowel lavage. It takes little prescience to predict an onslaught of future studies investigating the therapeutic potential of altering the human microbiome.
**Treatment**

- fluid and electrolyte replacement orally in most cases, intravenous if severe extremes of age/coma
- anti-diarrheals
  - antimotility agents: diphenoxylate, loperamide (Imodium®); contraindicated in mucosal inflammation
  - side effects: abdominal cramps, toxic megacolon
  - absorbants: kaolin/pectin (Kaopectate®), methylcellulose, activated attapulgite
    - act by absorbing intestinal toxins/micro-organisms, or by coating intestinal mucosa
    - much less effective than antimotility agents
  - modifiers of fluid transport: bismuth subsalicylate (Pepto-Bismol®) may be helpful (but should not be used in the presence of bloody diarrhea or fever)
- antibiotics: rarely indicated
  - risks
    - prolonged excretion of enteric pathogen (especially Salmonella)
    - drug side effects (including C. difficile infection)
    - development of resistant strains
    - renal failure/hemolysis (enterohemorrhagic E. coli O157:H7)
- indications for antimicrobial agents in acute diarrhea
  - septicemia
  - prolonged fever with fecal blood or leukocytes
  - clearly indicated: Shigella, V. cholerae, C. difficile, traveller’s diarrhea (enterotoxigenic E. coli [ETEC]), Giardia, Entamoeba histolytica, Cyclospora
  - situational: Salmonella, Campylobacter, Yersinia, non-enterotoxigenic E. coli
  - Salmonella: always treat Salmonella typhi (typhoid or enteric fever); treat other Salmonella only if there is underlying immunodeficiency, hemolytic anemia, extremes of age, aneurysms, prosthetic valve grafts/joints, sickle cell disease

**Figure 7. Approach to acute diarrhea**

*Note: S. typhi has a rose spot rash (transient maculopapular rash on anterior thorax, upper abdomen), and a prodrome of high fever, bradycardia, headache, and abdominal pain. Diarrhea is not the initial presentation*

### Traveller’s Diarrhea

#### Epidemiology
- most common illness to affect travellers
- up to 50% of travellers to developing countries affected in first 2 wk and 10-20% after returning home

#### Etiology
- bacterial (80-90%): *E. coli* most common (ETEC), *Campylobacter, Shigella, Salmonella, Vibrio* (non-cholera); wide regional variation (e.g. *Campylobacter* more common in Southeast Asia)
- viral: norovirus, rotavirus, and astrovirus account for 5-8%
- protozoal (rarely): *Giardia, Entamoeba histolytica, Cryptosporidium, and Cyclospora* for ~10% in long-term travellers
- pathogen-negative traveller’s diarrhoea common despite exhaustive microbiological workup

#### Treatment
- rehydration is the mainstay of therapy
  - rehydrate with sealed beverages
  - in severe fluid loss, use oral rehydration solutions (1 package in 1 L boiled or treated water)
  - treat symptoms: antidiarrheal agents (e.g. rifamycin antibiotics, bismuth salicylate, loperamide)
  - empiric antibiotics in moderate or severe illness: ciprofloxacin or azithromycin or rifaximin
  - note: there is increasing fluoroquinolone resistance in causative agents, especially in South and Southeast Asia

#### Prevention
- proper hygiene practices
  - avoid consumption of: foods or beverages from establishments with unhygienic conditions (e.g. street vendors), raw fruits or vegetables without a peel, raw or undercooked meat and seafood
  - avoid untreated water
  - bismuth salicylate (Pepto-Bismol®): 60% effective (2 tablets qid according to CDC website)
  - CDC Guidelines: antibiotic prophylaxis not recommended
  - increased risk of infection with resistant organisms
  - high risk groups (e.g. immunocompromised) likely to be infected with pathogen not covered by standard antimicrobial agents
• Dukoral®: oral vaccine that offers protection against *V. cholerae* (efficacy ~80%) and ETEC (efficacy ~50-67%)
  - Public Health Agency of Canada recommends that it may be considered for the following situations (not recommended for routine use in travellers):
    • short-term travellers >2 yr old who are high-risk (e.g. chronic illness) for whom there is an increased risk of serious consequences for traveller's diarrhea (e.g. chronic renal failure, CHF, type 1 DM, inflammatory bowel disease)
    • immunosuppressed
    • history of repeat traveller's diarrhea
    • increased risk of acquiring traveller's diarrhea (gastric hypochlorhydria or young children >2 yr)
    • travellers to cholera endemic countries at increased risk of exposure
  - two vaccines against *Salmonella typhi* are available and their effectiveness is estimated to be between 50-70%

### Chronic Diarrhea

**Definition**
- passage of frequent unformed stool for >4 wk (persistent diarrhea as 14-30 d)
- approach is similar to that of acute diarrhea except that the majority of cases are non-infectious

**Etiology/Classification**
- see *Differential Diagnosis of Common Presenting Complaints, G4*

**Investigations**
- guided by history
- stool analysis for: *C. difficile* toxin, C&S, O&P ± fecal fat, WBC
- blood for: CBC, electrolytes, CRP, TSH, celiac serology (IgA anti-tTG; ask for serum protein electrophoresis or immunoglobulin quantitation to rule out IgA deficiency which has an increased frequency in celiac disease)
- colonoscopy and ileoscopy with biopsy
- wireless small bowel endoscopy capsule (low yield)
- trial of lactose free diet
  - caveat: may delay diagnosis of IBD and celiac disease

### Maldigestion and Malabsorption

**Definition**
- maldigestion: inability to break down large molecules in the lumen of the intestine into their component small molecules
- malabsorption: inability to transport molecules across the intestinal mucosa into circulation

**Etiology**
- maldigestion
  - inadequate mixing of food with enzymes (e.g. post-gastrectomy)
  - pancreatic exocrine deficiency
  - primary diseases of the pancreas (e.g. cystic fibrosis [remember CF can result in pancreatic exocrine insufficiency as well], pancreatitis, cancer)
  - bile salt deficiency
    - terminal ileal disease (impaired recycling in view of loss greater than synthesis), bacterial overgrowth (deconjugation of bile salts), rarely liver disease (cholestatic, e.g. primary biliary cirrhosis)
  - specific enzyme deficiencies (e.g. lactase)
- malabsorption
  - inadequate absorptive surface
    - infections/infestations (e.g. Whipple's disease, Giardia)
    - immunologic or allergic injury (e.g. celiac disease)
  - infiltration (e.g. lymphoma, amyloidosis)
  - fibrosis (e.g. systemic sclerosis, radiation enteritis): fibrosis can lead to loss of surface area but also areas of stasis with small bowel overgrowth
  - small bowel resection (length, site, location, presence/absence of ileocecal valve and integrity of colon are important)
  - congenital (e.g. short bowel syndrome)
  - inflammatory: extensive ileal Crohn's disease (pivotal number is 100 cm as <100 cm = bile salt or choleretic diarrhea, >100 cm = fatty diarrhea or steatorrhea)
  - drug-induced
    - cholestyramine, ethanol, neomycin, tetracycline, and other antibiotics
  - endocrine
    - DM (complex pathogenesis)
Clinical Features
- Symptoms usually vague unless disease is severe
- Weight loss, diarrhea, steatorrhea, weakness, fatigue
- Manifestations of malabsorption/deficiency

</tbody>
</table>

* Calcium malabsorption more commonly causes decreased bone density rather than hypocalcemia because serum calcium levels are protected by leaching calcium from the bone.

Investigations
- Tissue transglutaminase (tTG) antibody serology/immunoglobulin A quantitation and abdominal imaging are most useful because celiac disease and chronic pancreatitis are the two most common causes of steatorrhea
- 72 h stool collection (weight, fat content) documents steatorrhea (gold standard)
- Fecal elastase to screen for pancreatic insufficiency and/or consider empiric trial of pancreatic enzymes based on clinical context
- Serum carotene (precursor to vitamin A), folate, Ca\(_2+\), Mg\(_2+\), vitamin B12, albumin, ferritin, serum iron solution, INR/PTT
- Stool fat globules on fecal smear stained with Sudan (used as an initial screening tool)
- Other tests specific for etiology (e.g. CT scan/MRI to visualize pancreas)

Treatment
- Dependent on underlying etiology
Celiac Disease (Gluten Enteropathy/Sprue)

Definition
• abnormal small intestine mucosa due to intestinal reaction to gluten, a protein found in wheat, barley, rye, and possibly oats (certified gluten-free oats may be acceptable in a subgroup of patients)

Etiology
• the only autoimmune disease in which autoantigen (various gliadin peptides) is recognized
• associated with other autoimmune diseases, especially Sjögren’s, thyroid disease, DM Type 1
• gluten is broken down to gliadin, which is the toxic factor
• HLA-DQ2 (chromosome 6) found in 80-90% of patients compared with 20% in general population; celiac also associated with HLA-DQ8 (note: up to 40% of Caucasians carry the HLA alleles, but will never develop celiac disease)

Epidemiology
• more common in women
• family history: 10-15% of first-degree relatives
• may present any time from infancy (when cereals introduced) to elderly
• peak presentation in infancy

Clinical Features
• classic presentation: diarrhea, weight loss, anemia, symptoms of vitamin/mineral deficiency, failure to thrive; more common current presentation: bloating, gas, iron deficiency
• improves with gluten-free diet, deteriorates when gluten reintroduced
• disease is usually most severe in proximal bowel
  • iron, calcium, and folic acid deficiency (proximal absorption) more common than vitamin B12 deficiency (absorbed in ileum)
• gluten enteropathy may be associated with dermatitis herpetiformis skin eruption, epilepsy, myopathy, depression, paranoia, infertility, bone fractures/metabolic bone disease

Investigations
• serological tests
  • serum anti-tTG antibody, IgA, is 90-98% sensitive, 94-97% specific
  • patients with selective IgA deficiency have false-negative anti-tTG
    • therefore, measure serum IgA concomitantly (via serum immunoglobulin quantitation)
• incorporate serum testing tTG and/or DGP IgG in IgA deficiencies
• small bowel mucosal biopsy (usually duodenum) is diagnostic with increased intraepithelial lymphocytes (earliest pathologic finding)
  • crypt hyperplasia
  • villous atrophy
  • note: villous atrophy also seen in small bowel overgrowth, Crohn’s, lymphoma, Giardia, HIV
• improvement with a gluten-free diet, but should not be started before serological tests and biopsy
• consider CT enterography to visualize small bowel to rule out lymphoma
• evidence of malabsorption (localized or generalized)
  • steatorrhea
  • low levels of ferritin/iron saturation, Ca++, Fe, albumin, cholesterol, carotene, B12 absorption
• quantitative fecal fat >7%

Treatment
• dietary counselling
  • gluten free diet; avoid barley, rye, wheat (as these grains are related and also have toxic factor, similar to gliadin)
  • oats allowed if not contaminated by other grains (grown in soil without cross-contamination)
  • rice and corn flour are acceptable
  • iron, folate supplementation (with supplementation of other vitamins as needed)
• if poor response to diet change, consider
  • alternate diagnosis
  • non-adherence to gluten-free diet
• concurrent disease (e.g. microscopic colitis, pancreatic insufficiency)
• development of intestinal (enteropathy-associated T-cell) lymphoma (abdominal pain, weight loss, palpable mass)
• development of diffuse intestinal ulceration, characterized by aberrant intraepithelial T-cell population (precursor to lymphoma)

Prognosis
• associated with increased risk of lymphoma, carcinoma (e.g. small bowel and colon; slight increase compared with general population), autoimmune diseases
• risk of lymphoma may be lowered by dietary gluten restriction
**Inflammatory Bowel Disease**

**Definition**
- complex, multifactorial etiology
- most likely a sustained response of the immune system, perhaps to enteric flora
- lack of appropriate down-regulation of immune responsiveness after an infection in a genetically predisposed individual

**Genetics**
- increased risk of both UC and CD in relatives of patients with either disease, especially siblings, early onset disease
  - familial risk greater if proband has CD rather than UC
- likely polygenomic pattern: 9 gene loci are associated
  - CARD15/NOD2 gene mutation associated with CD (relative risk in heterozygote is 3, in homozygote is 40), especially in Ashkenazi Jews, early onset disease, ileal involvement, and fistulizing, fibrostenotic or structuring disease
  - CARD15 gene product modulates NFκβ, which is required for the innate immune response to microbial pathogens, best expressed in monocytes-macrophages

**Crohn’s Disease**

**Definition**
- Chronic transmural inflammatory disorder potentially affecting the entire gut from mouth to perianal region (“gum to bum”)

**Epidemiology**
- Worldwide incidence 3-15 to 10-20/100,000; 135,000 Canadians living with Crohn’s
- Bimodal: onset before 30 yr, second smaller peak age 60; M=F
- Incidence of Crohn’s increasing (relative to UC) especially in young females
- More common in Caucasians, Ashkenazi Jews
  - Risk in Asians increases with move to Western countries
- Smoking incidence in Crohn’s patients is higher than general population

**Pathology**
- Most common location: ileum + right colon
- Linear ulcers leading to mucosal islands and “cobblestone” appearance
- Granulomas are found in 50% of surgical specimens, 15% of mucosal biopsies

**Clinical Features**
- Natural history unpredictable; young age, perianal disease, and need for corticosteroids have been associated with poor prognosis, but associations are not strong enough to guide clinical decisions
- Most often presents as recurrent episodes of abdominal cramps, non-bloody diarrhea, and weight loss
- Ileitis may present with post-prandial pain, vomiting, RLQ mass; mimics acute appendicitis
- Extra-intestinal manifestations are more common with colonic involvement
- Fistulae, fissures, abscesses are common
- Deep fissures with risk of perforation into contiguous viscera (leads to fistulae and abscesses)
- Enteric fistulae may communicate with skin, bladder, vagina, and other parts of bowel

**Investigations**
- Colonoscopy with biopsy to visualize (less often gastroscopy)
- CT/MR enterography to visualize small bowel
- CRP elevated in most new cases, useful to monitor treatment response (especially acutely in UC)
- Bacterial cultures, O&P, C. difficile toxin to exclude other causes of inflammatory diarrhea

**Management** (see Figure 8)
Table 15. Management of Crohn’s Disease

<table>
<thead>
<tr>
<th>Management</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Lifestyle/Diet</strong></td>
<td></td>
</tr>
<tr>
<td>Smoking cessation</td>
<td></td>
</tr>
<tr>
<td>Fluids only during acute exacerbation</td>
<td></td>
</tr>
<tr>
<td>Enteral diets may aid in remission only for Crohn’s ileitis, not colitis</td>
<td></td>
</tr>
<tr>
<td>No evidence for any non-enteral diet changing the natural history of Crohn’s disease, but may affect symptoms</td>
<td></td>
</tr>
<tr>
<td>Those with extensive small bowel involvement or extensive resection require electrolyte, mineral, and vitamin supplements (vitamin D, Ca²⁺, Mg²⁺, zinc, Fe, B₁₂)</td>
<td></td>
</tr>
<tr>
<td><strong>Antidiarrheal Agents</strong>*</td>
<td></td>
</tr>
<tr>
<td>Loperamide (Imodium®) &gt; diphenoxylate (Lomotil®) &gt; codeine (cheap but addictive)</td>
<td></td>
</tr>
<tr>
<td>All work by decreasing small bowel motility, used only for symptom relief</td>
<td></td>
</tr>
<tr>
<td>CAUTION if colitis is severe (risk of precipitating toxic megacolon), therefore avoid during flare-ups</td>
<td></td>
</tr>
<tr>
<td><strong>5-ASA</strong></td>
<td></td>
</tr>
<tr>
<td>Efficacy controversial: is currently used for mild ileitis</td>
<td></td>
</tr>
<tr>
<td>Sulfasalazine (Salazopyrin®): 5-ASA bound to sulfapyridine</td>
<td></td>
</tr>
<tr>
<td>Hydrolysis by intestinal bacteria releases 5-ASA (active component)</td>
<td></td>
</tr>
<tr>
<td>Dose-dependent efficacy</td>
<td></td>
</tr>
<tr>
<td>Mesalamine (Fentass®): coated 5-ASA releases 5-ASA in the ileum and colon when inflammation is mild</td>
<td></td>
</tr>
<tr>
<td>Antibiotics</td>
<td></td>
</tr>
<tr>
<td>e.g. metronidazole (20 mg/kg/d, bid or tid dosing) or ciprofloxacin</td>
<td></td>
</tr>
<tr>
<td>Best described for perianal Crohn’s, although characteristically relapse when discontinued</td>
<td></td>
</tr>
<tr>
<td><strong>Corticosteroids</strong></td>
<td></td>
</tr>
<tr>
<td>Prednisone: starting dose 40 mg OD for acute exacerbations; IV methylprednisolone if severe</td>
<td></td>
</tr>
<tr>
<td>No proven role for steroids in maintaining remissions; masks intra-abdominal sepsis</td>
<td></td>
</tr>
<tr>
<td><strong>Immunosuppressives</strong></td>
<td></td>
</tr>
<tr>
<td>6-mercaptopurine (6-MP), azathioprine (Imuran®); methotrexate (used less often)</td>
<td></td>
</tr>
<tr>
<td>More often used to maintain remission than to treat active inflammation</td>
<td></td>
</tr>
<tr>
<td>Most commonly used as steroid-sparing agents</td>
<td></td>
</tr>
<tr>
<td>i.e. to lower risk of relapse as corticosteroids are withdrawn</td>
<td></td>
</tr>
<tr>
<td>May require &gt;3 mo to have beneficial effect; usually continued for several years</td>
<td></td>
</tr>
<tr>
<td>May help to heal fistulae, decrease disease activity</td>
<td></td>
</tr>
<tr>
<td>Increases efficacy of biologics plus lowers chances of biological dosing efficacy (tolerance) so often given in combination with biologics</td>
<td></td>
</tr>
<tr>
<td>Side effects: vomiting, pancreatitis, bone marrow suppression, increased risk of malignancy (i.e. lymphoma)</td>
<td></td>
</tr>
<tr>
<td><strong>Biologics</strong></td>
<td></td>
</tr>
<tr>
<td>Infliximab IV (Remicade®) or adalimumab SC (Humira®): both = antibody to TNF-α</td>
<td></td>
</tr>
<tr>
<td>Proven effective for treatment of fistulae and patients with medically refractory CD</td>
<td></td>
</tr>
<tr>
<td>First-line immunosuppressive therapy with infliximab + azathioprine more effective than using either alone</td>
<td></td>
</tr>
<tr>
<td>Ustekinumab, monoclonal antibody against P40 subunit of interleukin 12 and 23</td>
<td></td>
</tr>
<tr>
<td>Vedolizumab, monoclonal antibody directed against integrin α₄β₇ thereby reducing lymphocyte traffic to gut -- now indicated for UC and Crohn’s</td>
<td></td>
</tr>
<tr>
<td><strong>Surgical/Experimental</strong></td>
<td></td>
</tr>
<tr>
<td>Surgical treatment (see General Surgery, GS33)</td>
<td></td>
</tr>
<tr>
<td>Surgery generally reserved for complications such as fistulae, obstruction, abscess, perforation, bleeding, and for medically refractory disease</td>
<td></td>
</tr>
<tr>
<td>At least 50% clinical recurrence within 5 yr; 85% within 15 yr; endoscopic recurrence rate even higher</td>
<td></td>
</tr>
<tr>
<td>40% likelihood of second bowel resection, 30% likelihood of third bowel resection</td>
<td></td>
</tr>
<tr>
<td>Complications of ileal resection</td>
<td></td>
</tr>
<tr>
<td>&lt;100 cm resected → watery diarrhea or cholorrhea (impaired bile salt absorption)</td>
<td></td>
</tr>
<tr>
<td>Treatment: cholestyramine or anti-diarrheals e.g. loperamide</td>
<td></td>
</tr>
<tr>
<td>&gt;100 cm resected → steatorrhea (reduced mucosal surface area, bile salt deficiency)</td>
<td></td>
</tr>
<tr>
<td>Treatment: fat restriction, medium chain triglycerides</td>
<td></td>
</tr>
<tr>
<td>*Cholestyramine: a bile-salt binding resin; for watery diarrhea with &lt;100 cm of terminal ileum diseased or resected; however, non-specific anti-diarrheals are more convenient and often more potent</td>
<td></td>
</tr>
<tr>
<td><strong>5-ASA use in Crohn’s is controversial; however, initial trial for mild ileitis only is warranted (induction and maintenance if clinical response)</strong></td>
<td></td>
</tr>
</tbody>
</table>

**Prognosis**
- highly variable course
- 10% disabled by the disease eventually, spontaneous remission also described
- increased mortality, especially with more proximal disease, greatest in the first 4-5 yr
- complications include
  - intestinal obstruction/perforation
  - fistula formation
  - malignancy (lower risk compared to UC)
- surveillance colonoscopy same as ulcerative colitis (see Ulcerative Colitis) if more than 1/3 of colon involved

**Ulcerative Colitis**

**Definition**
- inflammatory disease affecting colonic mucosa anywhere from rectum (always involved) to cecum

**Epidemiology**
- worldwide incidence 3-15 to 10-20/100,000; 120,000 Canadians living with UC (less common than Crohn’s)
- 2/3 onset by age 30 (with second peak after 50); M=F
- small hereditary contribution (15% of cases have 1st degree relative with disease)
- risk is less in smokers
- inflammation limited to rectum or left colon is more common than pancolitis
Pathology
- disease can involve any portion of lower bowel ranging from rectum only (proctitis) to entire colon (pancolitis)
- inflammation is diffuse, continuous and confined to mucosa

Clinical Features
- rectal bleeding is the hallmark feature; diarrhea present if more than the rectum is involved
  - can also have abdominal cramps/pain, especially with defecation
  - severity of colonic inflammation correlates with symptoms (stool volume, amount of blood in stool)
  - tenesmus, urgency, incontinence
  - systemic symptoms: fever, anorexia, weight loss, fatigue in severe cases
  - extra-intestinal manifestations (see Table 14, G23)
  - characteristic exacerbations and remissions; 5% of cases are fulminant

Investigations
- sigmoidoscopy with mucosal biopsy (to exclude self-limited colitis) without bowel prep often sufficient for diagnosis
- colonoscopy helpful to determine extent of disease; contraindicated in severe exacerbation
- CT colonography (formerly barium enema) if colonoscopy cannot be done; contraindicated in severe disease
- stool culture, microscopy, C. difficile toxin assay necessary to exclude infection
- no single confirmatory test

Treatment
- mainstays of treatment: 5-ASA (mesalamine) derivatives (only in mild to moderate disease) and corticosteroids, with azathioprine used in steroid-dependent or resistant cases
- diet of little value in decreasing inflammation but may alleviate symptoms
- anti-diarrheal medications generally not indicated in UC
  - 5-ASA
    - topical (suppository or enema): effective for distal disease (rectum to splenic flexure) if inflammation is mild, preferable to corticosteroids
    - oral: effective for mild to moderate, but not severe colitis (e.g. sulfasalazine 3-4 g/d, mesalamine 4 g/d)
    - commonly used in maintaining remission (decreases yearly relapse rate from 60% to 15%)
    - may decrease rate of colorectal cancer
  - corticosteroids
    - to remit acute disease, especially if severe or first attack; may need maximum dose IV steroids initially (e.g. methylprednisolone 30 mg IV q12h)
    - limited role as maintenance therapy for mild to moderate disease
    - use suppositories (predominantly available in compound pharmacies) for proctitis
    - use enemas and topical steroids (e.g. hydrocortisone foam, budesonide enemas) for inflammation distal to splenic flexure
  - immunosuppressants (steroid-sparing)
    - in hospitalized patients with severe UC – add IV infliximab if no response to IV methylprednisolone within 3 d; then consider colectomy if inadequate response
    - biologics (infliximab, adalimumab, golimumab, vedolizumab, tofacitinib) can also be used for outpatients with moderate-severe disease, particularly those that are steroid-unresponsive or steroid-dependent, some evidence that they are best used early in course of disease
    - azathioprine and 6-mercaptopurine: too slow to rapidly resolve acute relapse
    - most commonly used to maintain remission as corticosteroids withdrawn
    - given with biologics: increase efficacy of infliximab and decrease likelihood of developing tolerance to infliximab (~10% chance/yr)
  - surgical treatment curative
    - aim for cure with colectomy; bowel continuity can be restored with ileal pouch-anal anastomosis (IPAA)
    - indications: failure of adequate medical therapy, toxic megacolon, uncontrollable bleeding, precancerous changes detected either by endoscopy or endoscopic biopsies (dysplasia), inability to taper corticosteroids, overt malignancy

Complications
- similar to CD, except:
  - more liver problems (especially PSC in men)
  - greater risk of colorectal cancer
    - risk increases with duration and extent of disease (5% at 10 yr, 15% at 20 yr for pancolitis; overall relative risk is 8%)
    - risk also increases with active mucosal inflammation and sclerosing cholangitis
    - thus, regular colonoscopy and biopsy in pancolitis if ≥8 yr is indicated
  - toxic megacolon (transverse colon diameter >6 cm on abdominal x-ray) with immediate danger of perforation (see General Surgery, GS42)
Prognosis
- chronic relapsing pattern in most patients
- 10-15% chronic continuous pattern
- >1 attack in almost all patients
- more colonic involvement in the 1st yr correlates with increased severity of attacks and increased colectomy rate
  - colectomy rate = 1% for all patients after the 1st yr; 20-25% eventually undergo colectomy
- normal life expectancy
- if proctitis only, usually benign course, lifetime risk of extension is 15%
- stool calprotectin increasingly recognized as a marker of bowel mucosal inflammation, reported especially to be useful in monitoring the activity of inflammatory bowel disease, but accuracy is still controversial

Irritable Bowel Syndrome

Definition
- a form of functional bowel disease; more than just a label for GI symptoms unexplained after normal investigations

Epidemiology
- 11% worldwide prevalence
- onset of symptoms usually in young adulthood
- F>M

Clinical Features
- Rome IV Criteria are used for diagnosis
- diagnosis is based chiefly on history; no specific diagnostic test available

Pathophysiology
- associated with either abnormal perception of intestinal activity or abnormal intestinal motility
- abnormal motility: multiple abnormalities described; unclear if associations or if causative
- psychological: stress may increase IBS symptoms but probably does not cause IBS
- 4 main types of IBS
  - IBS-D: IBS with predominant diarrhea
  - IBS-C: IBS with predominant constipation
  - IBS-M: IBS-mixed with both diarrhea and constipation (each >25% of all abnormal bowel movements)
  - IBS untyped: insufficient abnormality in stool consistency to meet other types

Diagnosis

Table 16. Rome IV Criteria for Diagnosing Irritable Bowel Syndrome

<table>
<thead>
<tr>
<th>IBS Rome IV Criteria</th>
</tr>
</thead>
<tbody>
<tr>
<td>Recurrent abdominal pain for more than 6 mo, of at least 1/d/wk in the last 3 mo, associated with 2 or more of the following:</td>
</tr>
<tr>
<td>1. Related to defecation</td>
</tr>
<tr>
<td>2. Associated with a change in frequency of stool</td>
</tr>
<tr>
<td>3. Associated with a change in form (appearance) of stool</td>
</tr>
<tr>
<td>Symptom onset at least 6 mo before diagnosis and criteria present during the last 3 mo</td>
</tr>
<tr>
<td>The following are supportive, but not essential to the diagnosis:</td>
</tr>
<tr>
<td>Abnormal stool frequency (&gt;3/d or &lt;3/wk)</td>
</tr>
<tr>
<td>Abnormal stool form (lumpy/hard/loose/watery) &gt;1/4 of defecations</td>
</tr>
<tr>
<td>Abnormal stool passage (straining, urgency, feeling of incomplete evacuation) &gt;1/4 of defecations</td>
</tr>
<tr>
<td>Passage of mucus &gt;1/4 of defecations</td>
</tr>
<tr>
<td>Bloating</td>
</tr>
</tbody>
</table>

Diagnosis of IBS Less Likely in Presence of “Red Flag” Features

<table>

<th>Weight loss</th>
<th>Anemia</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fever</td>
<td>Blood or pus in stool</td>
</tr>
<tr>
<td>Nocturnal defecation</td>
<td>Abnormal gross findings on flexible sigmoidoscopy</td>
</tr>
</tbody>
</table>

Normal Physical Exam

Investigations
- if history consistent with Rome IV criteria, no alarm symptoms, and no family history of IBD or colorectal cancer, limited investigations required
- aim is to rule out diseases which mimic IBS, particularly celiac disease and IBD
- investigations can be limited to CBC, inflammatory markers (ESR, CRP) and celiac serology
- if available, fecal calprotectin is likely more reliable test to rule out IBD
- consider TSH, stool cultures depending on clinical circumstances
- consider colonoscopy (e.g. if alarming features present, family history of IBD or age >50)

Treatment
- education: reassurance, explanation, support, aim for realistic goals
- relaxation therapy, biofeedback, hypnosis, stress reduction, probably exercise
- dietary: low FODMAP (Fermentable Oligo-, Di-, Monosaccharides And Polyols) diet for pain, bloating gas, irregular bowel movements
• no therapeutic agent consistently effective, pain most difficult to control, no drug changes natural history so the drug should be “wanted, since it is not needed”
• symptom-guided treatment
  • pain predominant
    • antispasmodic medication before meals (e.g. hyoscine, pinaverium, trimebutine - low level evidence)
    • tricyclic antidepressants (TCA), selective serotonin reuptake inhibitors (SSRI - moderate level of evidence)
  • IBS-D
    • increase fibre (bran or psyllium) to increase stool consistency but may worsen abdominal gas (controversial)
    • gluten avoidance (gluten shown to alter barrier)
    • loperamide (Imodium®)
    • diphenoxylate (Lomotil®)
    • cholestyramine
    • eluxadoline
    • rifaxamin
  • IBS-C
    • increase fibre in diet
    • linaclotide
    • osmotic or other laxatives (help more with the constipation than the pain)

Prognosis
• 80% improve over time
• most have intermittent episodes
• normal life expectancy

**Constipation**

---

**Definition**
• passage of infrequent/hard stools and/or difficult stool evacuation (ex. straining, sensation of anorectal blockage)

**Epidemiology**
• increasing prevalence with age; F>M
• rare in Africa and India where stool weight is 3-4x greater than in Western countries

**Risk Factors**
• female sex
• older age

**Etiology**
• most common: functional, idiopathic attributed to colon dysmotility but this is difficult to measure
• organic causes: likely only if there are symptoms other than constipation
  • medication side effects (narcotics, antidepressants) are the most common
  • intestinal obstruction, left sided colon cancer (consider in older patients), and fecal impaction
• metabolic
  • DM
  • hypothyroidism
  • hypercalcemia, hypokalemia, uremia
• neurological
  • intestinal pseudo-obstruction
  • Parkinson’s disease
  • MS
• collagen vascular disease (e.g. scleroderma)
• painful anal conditions (e.g. fissures)

**Clinical Feature**
• overlaps with IBS
• stool firm, difficult to expel, passed with straining, abdominal pain relieved by defecation, flatulence, overflow diarrhea, tenesmus, abdominal distension, infrequent BMs (<3/wk)

**Investigations**
• underlying disease rarely found if constipation is the only presenting symptom
  • only test indicated in this situation is a CBC (2013 recommendation of American Gastroenterology Association), but also consider TSH, calcium, and glucose, X-ray of abdomen
• colon visualization (colonoscopy, CT colonography) if concomitant symptoms such as rectal bleeding, weight loss, anemia or age above 50
• if refractory to treatment, consider classification based on colon transit time; can measure colonic transit time with radio-opaque markers that are ingested and followed with a series of plain film abdominal x-rays (normal: 70 h)
  1. normal = misperception of normal defecation (IBS)
  2. prolonged throughout = “colonic inertia” (infrequent bowel movements with gas/bloating, tends to occur in youth)
  3. outlet obstruction = inability to coordinate pelvic floor muscles to empty rectum, straining, stool in rectum on digital exam, tends to occur in old age
• combination of 1 and 3 common

---

**Rifaximin Therapy for Patients with Irritable Bowel Syndrome Without Constipation**
*NEJM 2011;364:22-32*

**Purpose:** Previous evidence suggests that gut flora may play an important role in the pathophysiology of IBS. This study evaluated rifaximin, a minimally absorbed antibiotic, in treating IBS without constipation.

**Methods:** Two phase 3, double-blind, placebo-controlled trials (TARGET 1 and TARGET 2). 1399 patients who had IBS without constipation were randomly assigned to rifaximin (550 mg dose) or placebo, 3 times daily for 2 wk, with a follow-up of 10 wk. The primary endpoint was adequate self-reported relief of global IBS symptoms.

**Results:** Significantly more patients in the rifaximin group had adequate self-reported relief of global IBS symptoms compared to the placebo group during the first 4 wk after treatment (40.8% vs. 33.2% respectively). Also, more patients in the rifaximin group had adequate relief of bloating compared to the placebo group (39.5% vs. 29.1% respectively).

**Conclusions:** Rifaximin therapy for 2 wk provided significant relief of symptoms, bloating, abdominal pain, and stool consistency associated with IBS without constipation.
Treatment (in order of Increasing Potency)
- dietary fibre
- useful if mild or moderate constipation, but not if severe
- aim for 30 g daily, increase dose slowly
- surface-acting (soften and lubricate)
- docusate salts (likely limited efficacy based on evidence), mineral oils
- osmotic agents (effective in 2-3 d)
  - polyethylene glycol 3350, lactulose, sorbitol, magnesium salts (e.g. magnesium hydroxide, i.e. milk of magnesia), lactitol (β-galactosido-sorbitol)
- cathartics/stimulants (effective in 24 h)
  - senna, bisacodyl
- enemas and suppositories (e.g. saline enema, phosphate enema, glycerin suppository, bisacodyl suppository)
- prokinetic agents (prucalopride)
- linaclotide (secretagogue, increases water secretion into the intestinal lumen)

Upper Gastrointestinal Bleeding

Definition
- bleeding proximal to the ligament of Treitz, see Gastrointestinal Tract, G2 (75% of GI bleeds)

Etiology
- above the GE junction
  - epistaxis
  - esophageal varices (10-30%)
  - esophagitis
  - esophageal cancer
  - Mallory-Weiss tear (10%)
- stomach
  - gastric ulcer (20%) (see Peptic Ulcer Disease, G11)
  - erosive gastritis (e.g. from EtOH or post-surgery) (20%)
  - gastric cancer
- duodenum
  - ulcer in bulb (25%)
- aortoenteric fistula: usually only if previous aortic graft (see sidebar)
- coagulopathy (drugs, renal disease, liver disease)
- vascular malformation (Dieulafoy’s lesion, arteriovenous malformation)

Clinical Features
- in order of decreasing severity of the bleed: hematochezia (brisk upper GI bleed) > hematemesis > coffee ground emesis > melena > occult blood in stool

Treatment
- stabilize patient (1-2 large bore IVs, IV fluids, monitor)
- send blood for CBC, cross and type, platelets, PT, PTT, electrolytes, BUN, Cr, LFTs
- keep NPO
- consider NG tube to determine upper vs. lower GI bleeding in some cases
- IV PPI: decrease risk of rebleed if endoscopic predictors of rebleeding seen (see prognosis section)
  - given to stabilize clot, not to accelerate ulcer healing
  - if given before endoscopy, decreases need for endoscopic therapeutic intervention
- for variceal bleeds, octreotide 50 µg loading dose followed by constant infusion of 50 µg/h and antibiotics for those with cirrhosis (reduces risk of infections)
- consider IV erythromycin (or metoclopramide) to accelerate gastric emptying prior to gastroscopy to remove clots from stomach
- endoscopy (OGD): establish bleeding site + treat lesion
  - if bleeding peptic ulcer: most commonly used method of controlling bleeding is injection of epinephrine around bleeding point + thermal hemostasis (bipolar electrocoagulation or heater probe), less often thermal hemostasis may be used alone, but injection alone not recommended
  - endoclips
  - hemostatic spray

Prognosis
- 80% stop spontaneously
- peptic ulcer bleeding: low mortality (2%) unless rebleeding occurs (25% of patients, 10% mortality)
- endoscopic predictors of rebleeding (Forrest classification): spurt or ooze, visible vessel, fibrin clot
- can send home if clinically stable, bleed is minor, no comorbidities, endoscopy shows clean ulcer with no high risk predictors of rebleeding
- H2-antagonists should not be used since they impact minimally on rebleeding rates and need for surgery
- esophageal varices have a high rebleeding rate (55%) and mortality (29%)

Lancet 1974;2:306-307
**Small and Large Bowel**

**Figure 9. Approach to iron deficiency anemia**

### Esophageal Varices

**Etiology**
- almost always due to portal hypertension

**Clinical Features**
- characteristically massive upper GI bleeding

**Prognosis**
- risk of bleeding: 30% in 1st yr
- risk of rebleeding: 50-70% (20% mortality at 6 wk)

**Investigations**
- endoscopy

**Management**

1. Assess hemodynamic stability and resuscitate*
2. IV octreotide
   - Causes splanchnic vasoconstriction
   - Decreases portal collateral circulation and pressure
3. Endoscopic therapy: variceal ligation (EVL) or sclerotherapy

**Long-term treatment to decrease risk of recurrent bleed**
- β-blocker (e.g. nadolol)
- Repeat EVL/sclerotherapy
- Nitrates
- Follow-up

**PERSISTENT or RECURRENT bleed – treatment options**
- Transjugular intrahepatic portosystemic shunt (TIPS)
- Balloon tamponade
- Liver transplant

*IV ceftriaxone lowers risk of sepsis, especially spontaneous bacterial peritonitis

If varices isolated to stomach, think of splenic vein thrombosis

Gastric varices best treated by endoscopic injection of cyanoacetate ("crazy glue")

**Mallory-Weiss Tear**

**Definition**
- longitudinal laceration in gastric mucosa on lesser curvature near GE junction (20% straddle junction, 5% in distal esophagus)

**Etiology**
- due to rapid increases in gastric pressure from retching/vomiting against a closed glottis
- hiatus hernia usually present

**Clinical Features**
- hematemesis ± melena, classically following an episode of retching without blood
- can lead to fatal hematemesis

**Management**
- 90% stop spontaneously
- if persistent: endoscopy with epinephrine injection ± clips or surgical repair
Lower Gastrointestinal Bleeding

Definition
• bleed distal to ligament of Treitz

Etiology
• if blood per rectum with hemodynamic instability, rule out upper GI source
• diverticular (60% from right colon)
• vascular
  • angiodysplasia (small vascular malformations of the gut)
  • anorectal (hemorrhoids, fissures)
• neoplasm
  • cancer
  • polyps
• inflammation
  • colitis (ulcerative, infectious, radiation, ischemic)
• post-polypectomy

Clinical Features
• hematochezia
• anemia
• occult blood in stool
• occasionally melena due to slow small bowel or right-colonic course

Treatment
• treat underlying cause

Figure 11. Approach to hematochezia

</tr>
</tbody>
</table>

*Bilirubin
*canaliculus breakdown product of hemoglobin, metabolized in the reticuloendothelial system of liver, transported through biliary system, excreted via gut
*direct bilirubin = conjugated; indirect = unconjugated bilirubin

B. Tests of Liver Injury

- disproportionately increased AST or ALT = hepatocellular damage
  - ALT more specific to liver; AST from multiple sources (especially muscle)
  - elevation of both highly suggestive of liver injury
  - most common cause of elevated ALT is fatty liver
- disproportionately increased ALP (and GGT) = cholestasis (stasis of bile flow)
- if ALP is elevated alone, rule out bone disease by fractionating ALP and/or checking GGT
- if ALP elevation out of proportion to ALT/AST elevation, consider:
  1. obstruction of common bile duct (e.g. extraluminal = pancreatic cancer, lymphoma; intraluminal = stones, cholangiocarcinoma, sclerosing cholangitis, helminths)
  2. destruction of microscopic ducts (e.g. PBC)
  3. bile acid transporter defects (e.g. drugs, intrahepatic cholestasis of pregnancy)
  4. infiltration of the liver (e.g. liver metastases, lymphoma, granulomas, amyloid)

Acute Viral Hepatitis (General)

**Definition**

- viral hepatitis lasting <6 mo

**Clinical Features**

- most are subclinical
- flu-like prodrome may precede jaundice by 1-2 wk
  - nausea/vomiting, anorexia, headaches, fatigue, myalgia, low-grade fever, arthralgia, and urticaria (especially HBV)
- only some progress to icteric (clinical jaundice) phase, lasting days to weeks
  - pale stools and dark urine 1-5 d prior to icteric phase
  - hepatomegaly and RUQ pain
  - splenomegaly and cervical lymphadenopathy (10-20% of cases)

**Investigations**

- AST and ALT (>10-20x normal in hepatocellular necrosis)
- ALP minimally elevated
- viral serology, particularly the IgM antibody directed to the virus

**Treatment**

- supportive (hydration, diet)
- usually resolves spontaneously, but if severe HBV infection, treatment with entecavir should be considered; in anicteric hepatitis C, anti-viral treatment should be considered (see Hepatitis C Virus, G33)
- indications for hospitalization: encephalopathy, coagulopathy, severe vomiting, hypoglycemia

**Prognosis**

- poor prognostic indicators: comorbidities, persistently high bilirubin (>340 mmol; 20 mg/dL), increased INR, decreased albumin, hypoglycemia
Complications
- cholestasis (most commonly associated with HAV infection)
- hepatocellular necrosis: AST, ALT >10-20x normal, ALP and bilirubin minimally increased, increased cholestasis

Hepatitis A Virus
- RNA virus
- fecal-oral transmission; incubation period 4-6 wk
- diagnosed by elevated transaminases, positive anti-HAV IgM
- in children: characteristically asymptomatic
- in adults: fatigue, nausea, arthralgia, fever, jaundice, hepatomegaly
- can cause acute liver failure and subsequent death (<1-5%)
- can relapse (rarely), but never becomes chronic
- can cause acute liver failure and subsequent death (<1-5%)
- in adults: fatigue, nausea, arthralgia, fever, jaundice, hepatomegaly
- in children: characteristically asymptomatic
- diagnosed by elevated transaminases, positive anti-HAV IgM
- fecal-oral transmission; incubation period 4-6 wk
- RNA virus

Epidemiology
- 4 phases of chronic hepatitis B: not all carriers will go through all 4 phases, but all carriers will have positive HBsAg
  1. **immune tolerance**: extremely high HBV-DNA (>20,000 IU/mL), HBeAg positive, but normal ALT/AST; due to little immune control and minimal immune-mediated liver damage; characteristic of perinatal infection (or ‘incubation period’ in adult with newly-acquired HBV)
  2. **immune clearance** (or immuneactive): HBV-DNA levels (>20,000 IU/mL), HBeAg positive; due to immune attack on the virus and immune-mediated liver damage; characterized by progressive disease without treatment and increasing liver fibrosis (sometimes progressing to cirrhosis and/or hepatocellular carcinoma); likely to benefit from treatment
  3. **inactive carrier** (immune control): lower HBV-DNA (<2000 IU/mL), HBeAg negative, anti-HBe positive, ALT/AST normal; due to immune control without immune-mediated liver damage; risk of reactivation to phase 2 (clinically resembles acute hepatitis B), especially with immunosuppression e.g. corticosteroids or chemotherapy
  4. **HBeAg-negative chronic hepatitis** (immune escape) (“core or precore mutant”): elevated HBV-DNA (>2000 IU/mL), HBeAg negative because of pre-core or core promoter gene mutation, anti-HBe positive, ALT/AST high; characterized by progressive disease without treatment and increasing liver fibrosis (sometimes progressing to cirrhosis and/or hepatocellular carcinoma); likely to benefit from treatment

Figure 12. Time course of acute hepatitis B infection

Risk Factors for Contracting Hepatitis B
- Infants born to a hepatitis B-infected parent (maternal or paternal)
- Unprotected sexual intercourse (especially if multiple partners)
- Needle sharing (e.g. injection drug users)
- Travel to endemic regions
- Exposure to human blood, semen, and other bodily fluids

Risk Factors for Progression
- Endogenous factors
- HIV coinfection
- Old age at diagnosis

Risk Factors for Progression
- Endogenous factors
- HIV coinfection
- Old age at diagnosis

Clinical Features of Hepatitis B
- Many patients are asymptomatic, both in the acute and chronic phases
- Acute hepatitis can manifest as jaundice, nausea, arthritis, constitutional symptoms
- Patients with chronic hepatitis can be asymptomatic, experience exacerbations, develop extrahepatic complications (e.g. glomerular disease), or develop cirrhosis
Treatment
- counselling: 40% of men and 10% of women with perinatal infection without treatment will die from HBV-related complications
- prolonged immune-mediated damage leads to higher risk of liver fibrosis
- hepatocellular carcinoma screening with ultrasound q6mo, especially if high serum HBV-DNA levels,
cirrhosis, men, (age >40 in Asian men, >50 in Asian women, and >20 in African descent)
- consider pharmacological therapy if:
  1. HBeAg positive + HBV-DNA >20,000 IU/mL + elevated ALT
  2. HBeAg negative + HBV-DNA >2000 IU/mL + elevated ALT + stage ≥2 fibrosis on liver biopsy
- treat to prevent flare when placed on immunosuppressive therapy such as prednisone,
  chemotherapy, biologics, etc.
- treatment goal: reduce serum HBV-DNA to undetectable level
- treatment options: interferon, tenofovir, entecavir, lamivudine
- vaccinate against HAV if serology negative (to prevent further liver damage)
- follow blood and sexual precautions

Hepatitis D Virus
- defective RNA virus requiring HBeAg for entry into hepatocyte, therefore infects only patients with HBV; causes more aggressive disease than hepatitis B virus alone
- coinfection: acquire HDV and HBV at the same time
- HDV can present as Acute Liver Failure and/or accelerate progression to cirrhosis
- treatment: low-dose interferon (20% response) and liver transplant for end-stage disease

Hepatitis C Virus
- RNA virus (7 genotypes; genotype 1 is most common in North America)
- blood-borne transmission; sexual transmission is “inefficient”
- major risk factor: injection drug use
- other risk factors: blood transfusion received before 1992 (or received in developing world), tattoos,
intranasal cocaine use
- clinical manifestation develops 6-8 wk after exposure
  - symptoms mild and vague (fatigue, malaise, nausea) therefore not commonly diagnosed in acute stage

Diagnosis
- suspected on basis of elevated ALT/AST and positive serum anti-HCV
- diagnosis established by detectable HCV-RNA in serum
- virus genotype correlates with response to treatment but not prognosis
- serum HCV-RNA inversely correlates with response to treatment
- normal transaminases can have underlying cirrhosis on biopsy, but otherwise excellent prognosis

Treatment
- blood-borne precautions; vaccinate for hepatitis A and B if serology negative; avoid alcohol
- clearest indication for treatment is in subgroups likely to develop clinically significant liver disease,
i.e. persistently elevated transaminases, liver biopsy showing fibrosis/cirrhosis, and at least moderately severe necrosis/inflammation
- now that safe, effective cure is available, the risk/benefit ratio favours treating everyone with chronic hepatitis C
- treatment depends partly on genotype; length of treatment depends on degree of fibrosis, level of serum HCV-RNA, comorbidities, and previous treatment
- oral interferon-free regimens (for all genotypes) (e.g. sofosbuvir/ledipasvir, ombitasvir/paritaprevir/
  ritonavir+dasabuvir, or elbasvir/grazoprevir and sofosbuvir/velpatasvir) are now the standard of care
- with >90% success rate without significant side-effects including those who failed previous interferon-based treatment

Prognosis
- 80% of acute hepatitis C become chronic (of these 20% evolve to cirrhosis)
- risk of hepatocellular carcinoma increases if cirrhotic
- can cause cryoglobulinemia; associated with membranoproliferative glomerulonephritis, lymph
### Autoimmune Liver Disease

- **diagnosis of exclusion:** rule out viruses, drugs/alcohol, metabolic, or genetic causes
- **can be severe:** 40% mortality at 6 mo without treatment
- **extrahepatic manifestations**
  - sicca, Raynaud’s, thyroiditis, Sjögren’s, arthralgias
  - hypergammaglobulinemia (particularly elevated IgG)
  - typical auto-antibodies: antinuclear antibody (ANA) and/or anti-smooth muscle antibody
  - infrequently may see anti-LKM elevation (liver kidney microsome), especially in children
  - can have false positive viral serology (especially anti-HCV)
  - biopsy – perportal (zone 1) and interface inflammation and necrosis
- **treatment:** corticosteroids (80% respond) ± azathioprine (without this, most will relapse as corticosteroids are withdrawn)
**Drug-Induced Liver Disease**

- many different patterns of liver injury (i.e. hepatocellular, cholestatic, mixed, granulomatous, acute liver failure) can be seen in drug-induced liver injury and thus this requires a high index of suspicion.
- see: LiverTox for Information regarding drug-specific risks and patterns of hepatotoxicity (http://livertox.nih.gov)

### Specific Drugs

- acetaminophen
  - metabolized by hepatic cytochrome P450 system
  - can cause acute liver failure (transaminases >1000 U/L followed by jaundice and encephalopathy)
  - requires 10-15 g in healthy, 4-6 g in alcoholics/anticonvulsant users
  - mechanism: high acetaminophen dose saturates glucuronidation and sulfation elimination pathways → reactive metabolite is formed → covalently binds to hepatocyte membrane
  - presentation
    - first 24 h: nausea and vomiting (usually within 4-12 h of overdose)
    - 24-48 h: asymptomatic, but ongoing hepatic necrosis resulting in increased transaminases
    - >48 h: continued hepatic necrosis possibly complicated with acute liver failure or resolution
  - note: potential delay in presentation in sustained-release products
  - blood levels of acetaminophen correlate with the severity of hepatic injury, particularly if time of ingestion known
  - therapy
    - gastric lavage/emesis (if <2 h after ingestion)
    - oral activated charcoal
    - N-acetylcysteine (NAC, Mucomyst®) can be given PO or IV (most effective within 8-10 h of ingestion, but should be given no matter when time of ingestion)
      - promotes hepatic glutathione regeneration
      - no recorded fatal outcomes if NAC given before increase in transaminases
- chlorpromazine: cholestasis in 1% after 4 wk; often with fever, rash, jaundice, pruritus, and eosinophilia
- INH (isoniazid)
  - 20% develop elevated transaminases but <1% develop clinically significant disease
  - susceptibility to injury increases with age
- methotrexate
  - causes fibrosis/cirrhosis; increased risk in the presence of obesity, DM, alcoholism (i.e. with underlying risk for pre-existing fatty liver)
  - scarring develops without symptoms or changes in liver enzymes, therefore biopsy may be needed in long-term treatment
- amiodarone: can cause same histology and clinical outcome as alcoholic hepatitis
- others: azoles, statins, methyldopa, phenytoin, propylthiouracil (PTU), rifampin, sulfonamides, tetracyclines
- herbs: chaparral, Chinese herbs (e.g. germander, comfrey, bush tea)

### Wilson’s Disease

**Definition**
- autosomal recessive defect in copper elimination (gene ATP7B)

**Etiology**
- decreased biliary excretion of copper plus decreased incorporation of copper into ceruloplasmin
- worldwide incidence 1/40,000

**Clinical Features**
- liver: acute hepatitis, acute liver failure, chronic active hepatitis, cirrhosis, low risk of hepatocellular carcinoma
- eyes: Kayser-Fleischer rings (copper deposits in Descemet's membrane); more common in patients with CNS involvement, present in only 50% of isolated liver involvement
- CNS: basal ganglia (wing flapping tremor, Parkinsonism), cerebellum (dysarthria, dysphagia, incoordination, ataxia), cerebrum (psychosis, affective disorder)
- kidneys: Fanconi's syndrome (proximal tubule transport defects) and stones
- blood: intravascular hemolysis; may be initial presentation in fulminant hepatitis
- joints: arthritis, bone demineralization, calcifications

**Clinical Manifestations of Wilson’s Disease**

**ABCD**
- Asterixis
- Basal ganglia degeneration: suspect if parkinsonian features in the young
- Ceruloplasmin decreases
- Cirrhosis
- Corneal deposits (Kayser-Fleischer ring)
- Copper
- Dementia

**Hy’s Law:** drug-induced hepatocellular jaundice indicates a mortality of at least 10%
Liver

Investigations
- suspect if increased liver enzymes with clinical manifestations at young age (<40); especially combination of liver disease with dystonia, psychiatric symptoms
- screening tests
  1. reduced serum ceruloplasmin (<50% of normal)
  2. Kayser-Fleischer rings (usually require slit-lamp examination)
  3. increased urinary copper excretion (measure 24-hour urine copper)
- gold standard
  1. increased copper on liver biopsy by quantitative assay
  2. genetic analysis imperfect as many mutations in ATP7B are possible

Treatment
- 4 drugs available
  1. penicillamine chelates copper, poorly tolerated
  2. trientine chelates copper
  3. zinc impairs copper excretion in stool and decreases copper absorption from gut
  4. tetrathiomolybdate preferred if neurological involvement
- hepatic presentations are best treated with a trientine + zinc combination; neurologic presentations are best treated with zinc; maintenance therapy with zinc
- liver transplant in severe cases of liver failure
- screen relatives

Hemochromatosis

Definition
- excessive iron storage causing multiorgan system dysfunction (liver, in particular) with total body stores of iron increased to 20–40 g (normal 1 g)

Etiology
- primary (hereditary) hemochromatosis
  - hepcidin deficiency results in ongoing gut absorption of iron despite adequate iron stores
- secondary hemochromatosis
  - parenteral iron overload (e.g. transfusions)
  - chronic hemolytic anemia: thalassemia, pyruvate kinase deficiency
  - excessive iron intake

Epidemiology
- hereditary hemochromatosis most common in Northern European descent
- primarily due to the recessive gene, HFE (or high iron), which has a homozygous genetic prevalence of 1/400

Clinical Features
- usually presents with trivial elevation in serum transaminases
- liver: cirrhosis (less common nowadays due to earlier detection), HCC (200x increased risk)
- pancreas: DM, chronic pancreatitis
- skin: bronze or grey (due to melanin, not iron)
- heart: dilated cardiomyopathy
- pituitary: hypogonadotropic hypogonadism (impotence, decreased libido, amenorrhea)
- joints: arthralgia (any joint, but especially MCP joints), chondrocalcinosis

Investigations
- screening for individuals with clinical features and/or family history (1/4 chance of sibling having the disease)
  - transferrin saturation (free Fe²⁺/TIBC) >45%
  - serum ferritin >400 ng/mL
  - HFE gene analysis: 90% of primary hemochromatosis involves C282Y allele, while H63D and S65C alleles also commonly involved and screened
  - liver biopsy (generally used to detect cirrhosis or if potential for other causes of liver disease)
    - markers of advanced fibrosis: if any of the following are present at the time of diagnosis → age >40, elevated liver enzymes, or ferritin >1000
    - considered if compound heterozygote and potential other cause of liver injury (e.g. fatty liver, etc.)
    - if C282Y/C282Y and no markers of advanced fibrosis, then biopsy generally not needed
  - HCC screening if cirrhosis

Treatment
- phlebotomy: weekly or q2wk then lifelong maintenance phlebotomies q2-6mo
- deferoxamine if phlebotomy contraindicated (e.g. cardiomyopathy, anemia)
- primary hemochromatosis responds well to phlebotomy
- secondary hemochromatosis usually requires chelation therapy (administration of agents that bind and sequester iron, and then excreted)

Prognosis
- normal life expectancy if treated before the development of cirrhosis or DM
Alcoholic Liver Disease

Definition
- spectrum of diseases, ranging from:
  - fatty liver (common amongst individuals with alcohol use disorder): reversible if alcohol stopped
  - alcoholic hepatitis (35% of individuals with alcohol use disorder): usually reversible if alcohol stopped
  - cirrhosis (10-15% of individuals with alcohol use disorder): potentially irreversible

Pathophysiology
- several mechanisms, poorly understood
- ethanol oxidation to acetaldehyde
  - reduces NAD+ to NADH; increased NADH decreases ATP supply to liver, impairing lipolysis so fatty acids and triglycerides accumulate in liver
  - binds to hepatocytes evoking an immune reaction
- EtOH increases gut permeability leading to increased bacterial translocation
- alcohol metabolism causes:
  - relative hypoxia in liver zone III (near central veins; poorly oxygenated) > zone I (around portal tracts, where oxygenated blood enters)
  - necrosis and hepatic vein sclerosis
- histology of alcoholic hepatitis
  - ballooned (swollen) hepatocytes often containing Mallory bodies, characteristically surrounded by neutrophils
  - large fat globules
  - fibrosis: space of Disse and perivenular

Clinical Features
- >2-3 standard drinks/d in females and >3-6 standard drinks/d in men for >10 yr leads to cirrhosis, but only in about 10-20% of those who consume this amount daily on a continuous basis; cirrhosis risk increases with amount of alcohol consumed above threshold
- clinical findings do not accurately predict type of liver involvement
  - fatty liver
    - mildly tender hepatomegaly; jaundice rare
    - mildly increased transaminases <5x normal
  - alcoholic hepatitis
    - variable severity; mild to fatal liver failure
    - mild: stops drinking because feels unwell, resumes when feeling better (if assessed, findings of hepatitis, potentially mild jaundice, and mildly elevated INR)
    - severe: stops drinking but feels unwell, low grade fever, RUQ discomfort, increased white blood cell count – mimics RLL pneumonia and cholecystitis

Investigations
- blood tests are non-specific, but in general
  - AST:ALT >2:1 (both usually <300)
  - CBC: increased MCV, increased WBC often seen with alcoholic hepatitis but not necessarily in other alcohol-related liver injury
  - increased GGT

Treatment
- alcohol cessation (see Psychiatry, PS27)
  - Alcoholics Anonymous, disulfiram, naltrexone, acamprosate
  - multivitamin supplements (especially thiamine)
  - caution with drugs metabolized by the liver
  - prednisolone if severe alcoholic hepatitis based on Maddrey's discriminant function or MELD score as described in Prognosis
    - pentoxifylline less used since most definitive trial did not demonstrate efficacy

Prognosis
- Maddrey's discriminant function (based on PT and bilirubin) and Model for End-Stage Liver Disease (MELD) predict mortality and guide treatment (consideration for corticosteroids for severe disease based on Maddrey ≥ 32 or MELD ≥21)
- fatty liver: complete resolution with cessation of alcohol intake
- alcoholic hepatitis mortality
  - immediate: 30%-60% in the first 6 mo if severe
  - with continued alcohol: 70% in 5 yr
  - with cessation: 30% in 5 yr

Standard Drink Equivalent

<table>
<thead>
<tr>
<th>Standard Drink Equivalent</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 standard drink = 14 g EtOH</td>
<td>12 oz beer (5% alcohol)</td>
</tr>
<tr>
<td></td>
<td>5 oz wine (12-17%)</td>
</tr>
<tr>
<td></td>
<td>3 oz fortified wine (17-22%)</td>
</tr>
<tr>
<td></td>
<td>1.5 oz liquor (40%)</td>
</tr>
</tbody>
</table>

Tip: percentage alcohol multiplied by oz in 1 standard drink roughly equals 60

Biopsy + Histology of Alcoholic Hepatitis
- Hepatocyte necrosis with surrounding inflammation in zone III
- Mallory bodies (intracellular eosinophilic aggregates of cytokeratins)
- Chicken-wire fibrosis (network of intralobular connective tissue surrounding cells and venules)

GI Complications of Alcohol Abuse
- Esophagus
  - Mallory-Weiss tear
  - Esophageal varices (secondary to portal hypertension)
- Stomach
  - Alcoholic gastritis
- Pancreas
  - Acute pancreatitis
  - Chronic pancreatitis
- Liver
  - Alcoholic hepatitis
  - Fatty liver
  - Cirrhosis
  - Hepatic encephalopathy
  - Portal hypertension
  - Ascites
  - HCC
Non-Alcoholic Fatty Liver Disease

Definition
- spectrum of disorders characterized by macrovesicular hepatic steatosis, sometimes with inflammation and/or fibrosis
- most common cause of liver disease in North America

Etiology
- pathogenesis not well elucidated; insulin resistance implicated as key mechanism, leading to hepatic steatosis
- histological changes indistinguishable from those of alcoholic hepatitis despite negligible history of alcohol consumption

Risk Factors
- likely a component of the metabolic syndrome along with obesity, T2DM, HTN, hypertriglyceridemia
- rapid weight loss or weight gain

Clinical Features
- often asymptomatic
- may present with fatigue, malaise, and vague RUQ discomfort
- elevated serum triglyceride/cholesterol levels and insulin resistance

Investigations
- elevated serum AST, ALT ± ALP; AST/ALT <1
- presents as echogenic liver texture on ultrasound
- non-invasive testing of fibrosis: FIB4, NAFLD fibrosis score, Fibrotest, FibroScan®
- liver biopsy cannot distinguish fatty liver from alcohol vs non-alcoholic fatty liver, but considered when investigating alternative etiologies or assessing for level of fibrosis

Treatment
- mainstay is gradual weight loss (0.5-1 kg/wk) as rapid weight loss can worsen liver disease
- ideally, aim to lose at least 7-10% of body weight
- some evidence for vitamin E (800 U daily) if there is hepatic inflammation
- some evidence for benefits of coffee drinking (3 cups/d) and vitamin D

Prognosis
- most die from cardiovascular or cerebrovascular disease
- better prognosis than alcoholic hepatitis
  - <25% progress to cirrhosis over a 7-10 yr period
- risk of progression increases if inflammation or scarring occurs alongside fat infiltration (non-alcoholic steatohepatitis)
- other clinical indicators of unfavourable prognosis: DM, age, metabolic syndrome, higher levels of fibrosis

Acute Liver Failure (formerly Fulminant Hepatic Failure)

Definition
- severe decline in liver function characterized by coagulation abnormality (INR >1.5) and encephalopathy
- in setting of previously normal liver
- rapid (<26 wk duration)

Etiology
- drugs (especially acetaminophen), hepatitis B (measure anti-HBc, IgM fraction because sometimes HBV-DNA and even HBsAg rapidly becomes negative), hepatitis A, hepatitis C (rare), ischemic, idiopathic

Treatment
- correct hypoglycemia, monitor level of consciousness, prevent GI bleeding with PPI, monitor for infection and multiorgan failure (usually requires ICU)
- consider liver biopsy before INR becomes too high
- chief value of biopsy is to exclude chronic disease, less helpful for prognosis
- liver transplant (King's College criteria can be used as prognostic indicator): consider early, especially if time from jaundice to encephalopathy >7 d (e.g. not extremely rapid), age <10 or >40, cause is drug or unknown, bilirubin >300 µmol/L, INR >3.5, creatinine >200 µmol/L.
Cirrhosis

Definition
- liver damage characterized by diffuse distortion of the basic architecture with fibrosis and formation of regenerative nodules
- Biopsy gold standard for diagnosis
- Stage 1 cirrhosis is compensated and asymptomatic, can last for 10-20 yr with almost normal life expectancy
- Stage 2 cirrhosis is decompensation, typically development of ascites (most common), variceal bleeding, encephalopathy, characteristically presents abruptly even though histologically the liver fibrosis is gradually progressive

Etiology
- fatty liver (alcoholic or non-alcoholic fatty liver disease)
- chronic viral hepatitis (B, B+D, C; not A or E)
- autoimmune hepatitis
- drugs (e.g. chronic methotrexate or amiodarone use)
- hemochromatosis
- primary biliary cholangitis
- chronic hepatic congestion
  - cardiac cirrhosis (chronic right heart failure, constrictive pericarditis)
  - hepatic vein thrombosis (Budd-Chiari)
- cryptogenic (i.e. no identifiable cause, although many of these patients may represent “burnt-out non-alcoholic steatohepatitis [NASH]”)
- rare: Wilson's disease, Gaucher's disease, α1-antitrypsin deficiency

Investigations
- definitive diagnosis is histologic (liver biopsy)
- other tests may be suggestive
  - blood work: fall in platelet count <150 is the earliest finding, followed many years later with rise in INR, fall in albumin, rise in bilirubin, fall in glucose level (pre-terminal event)
  - FibroTest: combination of various clinical and biochemical markers that can predict degree of fibrosis
  - imaging
    - U/S is the primary imaging modality but only finds advanced cirrhosis
    - CT to look for varices, nodular liver texture, splenomegaly, ascites
    - Transient Ultrasound Elastography (FibroScan™): non-invasive tool using elastography (variable availability) for measuring liver compliance
      - rapidly replacing liver biopsy to determine extent of liver fibrosis and make the diagnosis of cirrhosis
  - gastroscopy: varices or portal hypertensive gastropathy

Treatment
- treat underlying disorder
- decrease insults (e.g. alcohol cessation, hepatotoxic drugs, immunize for Hep A and B if non-immune)
- follow patient for complications (esophageal varices, ascites, HCC defines stage 2 cirrhosis)
- prognosis: Child-Pugh Score and MELD score
- liver transplantation for end-stage disease if no alcohol for >6 mo; use MELD score

Score: 5-6 (Child’s A), 7-9 (Child’s B), 10-15 (Child’s C)

*Note: Child’s classification is rarely used for shunting (TIPS or other surgical shunts), but is still useful to quantitate the severity of cirrhosis
**Complications**

- hematologic changes in cirrhosis
  - pancytopenia from hypersplenism: platelets first, then WBC, then hemoglobin
  - decreased clotting factors resulting in elevated INR
  - relationship of INR to bleeding tendency is controversial; some patients may be hypocoagulable, others may be hypercoagulable
- variceal bleeds
  - half of patients with cirrhosis have gastroesophageal varices and one-third of these develop hemorrhage with an overall mortality of >30%
  - hepatic venous pressure gradient (HVPG) ≥10 mmHg is the strongest predictor of variceal development
  - treatment: resuscitation, antibiotic prophylaxis, vasoactive drugs (e.g. octreotide IV) combined with endoscopic band ligation or sclerotherapy, Transjugular Intrahepatic Portosystemic Shunt (TIPS)
- renal failure in cirrhosis
  - classifications
    - pre-renal (usually due to over-diuresis)
    - acute tubular necrosis
    - Hepatorenal Syndrome (HRS)
      - Type I: sudden and acute renal failure (rapid doubling of creatinine over 2 wk)
      - Type II: gradual increase in creatinine with worsening liver function (creatinine doubling over years)
    - HRS can occur at any time in severe liver disease, especially after:
      - overdiuresis or dehydration, such as diarrhea, vomiting, etc.
      - GI bleed
      - sepsis
    - treatment for hepatorenal syndrome (generally unsuccessful at improving long-term survival)
      - for type I HRS: octreotide + midodrine + albumin (increases renal blood flow by increasing systemic vascular resistance)
      - definitive treatment is liver transplant
  - hepatopulmonary syndrome
  - majority of cases due to cirrhosis, though can be due to other chronic liver diseases, such as non-cirrhotic portal HTN
  - thought to arise from ventilation-perfusion mismatch, intrapulmonary shunting and limitation of oxygen diffusion, failure of damaged liver to clear circulating pulmonary vasodilators vs. production of a vasodilating substance by the liver
  - clinical features
    - hyperdynamic circulation with cardiac output >7 L/min at rest and decreased pulmonary + systemic resistance (intrapulmonary shunting)
    - dyspnea, platypnea (increase in dyspnea in upright position, improved by recumbency), and orthodeoxia (desaturation in the upright position, improved by recumbency)
    - diagnosis via contrast-enhanced echocardiography: inject air bubbles into peripheral vein; air bubbles appear in left ventricle after third heartbeat (normal = no air bubbles; in ventricular septal defect, air bubbles seen <3 heart beats)
    - only proven treatment is liver transplantation

---

**Figure 14. Clinical features of liver disease**

**Hepatocellular Carcinoma**

- see General Surgery, GS49

**Liver Transplantation**

- see General Surgery, GS50
**Portal Hypertension**

**Definition**
- pressure gradient between hepatic vein pressure and wedged hepatic vein pressure (corrected sinusoidal pressure) $>5$ mmHg

**Pathophysiology**
- 3 sites of increased resistance (remember pressure = flow x resistance)
  - pre-sinusoidal (e.g. portal vein thrombosis, schistosomiasis, sarcoidosis)
  - sinusoidal (e.g. cirrhosis, alcoholic hepatitis)
  - post-sinusoidal (e.g. right-sided heart failure, hepatic vein thrombosis, veno-occlusive disease, constrictive pericarditis)

**Complications**
- GI bleeding from varices in esophagus, less commonly in stomach, even less frequently from portal hypertensive gastropathy
- ascites
- hepatic encephalopathy
- thombocytopenia
- renal dysfunction
- sepsis
- arterial hypoxemia

**Treatment**
- non-selective β-blockers (propranolol, nadolol, carvedilol) decrease risk of bleeding from varices
- TIPS: to decrease portal venous pressure
  - radiologically inserted stent between portal and hepatic vein via transjugular vein catheterization and percutaneous puncture of portal vein
  - can be used to stop acute bleeding or prevent rebleeding or treat ascites
  - complications: hepatic encephalopathy, deterioration of hepatic function
  - contraindicated with severe liver dysfunction, uncontrolled hepatic encephalopathy, and congestive heart failure
  - most commonly used as a “bridge” to liver transplant
- other surgically created shunts: portacaval, distal spleno-renal (Warren shunt) - all used only rarely in the modern era

**Hepatic Encephalopathy**

**Definition**
- spectrum of potentially reversible neuropsychiatric syndromes secondary to liver disease diagnosed after ruling out other causes for symptoms (e.g. structural/metabolic)

**Pathophysiology**
- portosystemic shunt around hepatocytes and decreased hepatocellular function increase level of systemic toxins (believed to be ammonia from gut, mercaptans, fatty acids, amino acids) which go to the brain

**Precipitating Factors**
- nitrogen load (GI bleed, protein load from food intake, renal failure, constipation)
- drugs (narcotics, CNS depressants)
- electrolyte disturbance (hypokalemia, alkalosis, hypoxia, hypovolemia)
- infection (spontaneous bacterial peritonitis)
- deterioration in hepatic function or superimposed liver disease

**Stages**
- I: apathy, restlessness, reversal of sleep-wake cycle, slowed intellect, impaired computational abilities, impaired handwriting
- II: asterixis, lethargy, drowsiness, disorientation
- III: stupor (rousable), hyperactive reflexes, extensor plantar response (upgoing Babinski)
- IV: coma (response to painful stimuli only)

**Investigations**
- clinical diagnosis: supported by laboratory findings and exclusion of other neuropsychiatric diseases
- rule out
  - non-liver-related neuropsychiatric disease in a patient with liver problems (e.g. alcohol withdrawal or intoxication, sedatives, subdural hematoma, metabolic encephalopathy)
  - causes of metabolic encephalopathy (e.g. renal failure, respiratory failure, severe hyponatremia, hypoglycemia)
- characteristic EEG findings: diffuse (non-focal), slow, high amplitude waves
- serum ammonia levels increased, but not often necessary to measure in routine clinical use

**Complications**
- deterioration in hepatic function or superimposed liver disease
- infection (spontaneous bacterial peritonitis)
- electrolyte disturbance (hypokalemia, alkalosis, hypoxia, hypovolemia)
- drugs (narcotics, CNS depressants)
- nitrogen load (GI bleed, protein load from food intake, renal failure, constipation)

**TIPS**
- to decrease portal venous pressure
- non-selective β-blockers (propranolol, nadolol, carvedilol) decrease risk of bleeding from varices

**Conclusion**
- Combinations of lactulose plus rifaximin is more effective than lactulose alone in the treatment of overt HE.
- Of the patients, 48 (76%) in group A (lactulose plus rifaximin) had complete reversal of HE (P<0.004). There was a significant decrease in mortality after treatment with lactulose plus rifaximin vs. lactulose and placebo (23.8% vs. 49.1%, P<0.05). There were significantly more deaths in group B because lactulose plus rifaximin vs. lactulose and placebo (23.8% vs. 49.1%, P<0.05). There were significantly more deaths in group B because of sepsis (group A vs. group B: 7:17, P=0.01), whereas there were no differences because of gastrointestinal bleed (group A vs. group B: 4:4, P=nonsignificant NS) and hepatorenal syndrome (group A vs. group B: 4:5, P=0.05). Patients in the lactulose plus rifaximin group had shorter hospital stay (6.6±3.4 vs. 8.2±4.6, P=0.001).

**Objectives**
- Efficacy and safety of rifaximin plus lactulose vs. lactulose alone in treatment of overt hepatic encephalopathy
- American J Gastroenterol 2013;108:1458-63
- Study: prospective double-blind RCT.
- Objective: Efficacy and safety of rifaximin plus lactulose vs. lactulose alone in treatment of overt HE.
- Results: Of the patients, 48 (76%) in group A (lactulose plus rifaximin 1200 mg/d, n=63) compared with 26 (56.5%) in group B (lactulose 15 g/L plus placebo) had complete reversal of HE (P=0.001). There was a significant decrease in mortality after treatment with lactulose plus rifaximin vs. lactulose and placebo (23.8% vs. 49.1%, P<0.05). There were significantly more deaths in group B because of sepsis (group A vs. group B: 7:17, P=0.01), whereas there were no differences because of gastrointestinal bleed (group A vs. group B: 4:4, P=nonsignificant NS) and hepatorenal syndrome (group A vs. group B: 4:5, P=0.05). Patients in the lactulose plus rifaximin group had shorter hospital stay (6.6±3.4 vs. 8.2±4.6, P=0.01).
- Conclusion: Combination of lactulose plus rifaximin is more effective than lactulose alone in the treatment of overt HE.
Liver

**Treatment**
- treat underlying precipitating factors
- decrease generation of nitrogenous compounds
  - routine protein restriction is no longer recommended given patients generally have concurrent malnutrition and muscle wasting; however, vegetable protein is better tolerated than animal protein
  - lactulose: titrated to achieve 2-3 soft stools/d
    - prevents diffusion of NH3 (ammonia) from the colon into blood by lowering pH and forming non-diffusible NH4 (ammonium)
    - serves as a substrate for incorporation of ammonia by bacteria, promotes growth in bowel lumen of bacteria which produce minimal ammonia
    - also acts as a laxative to eliminate nitrogen-producing bacteria from colon
  - oral rifaximin for both acute treatment and maintenance therapy has high level evidence for efficacy
- best acute treatment in comatose patient is lactulose enemas

**Ascites**

**Definition**
- accumulation of excess fluid in the peritoneal cavity

**Etiology**

Table 22. Serum-Ascites Albumin Gradient in the Evaluation of Ascites

<table>
<thead>

<td>Sarcoitis</td>
</tr>
<tr>
<td></td>
<td>Nephrotic syndrome*</td>
</tr>
</tbody>
</table>

* In nephrotic syndrome: decreased serum [Alb] to begin with therefore gradient not helpful

**Pathophysiology**
- key factor in pathogenesis is increased sodium (and water) retention by the kidney for reasons not fully understood. Theories include:
  - underfill hypothesis
  - overfill hypothesis
  - peripheral arterial vasodilation theory (most popular): as portal hypertension develops in cirrhosis, production of local mediators such as nitric oxide leads to splanchnic arterial vasodilation, ultimately pulling blood away from the systemic circulation and resulting in reduced effective arterial volume, which causes compensatory sodium and fluid retention by the kidneys (i.e. circulatory volume is increased, as per the overfill hypothesis, but effective volume is decreased as per the underfill hypothesis)

**Diagnosis**
- abdominal ultrasound
- physical exam (clinically detectable when >500 mL)
  - bulging flanks, shifting dullness, fluid-wave test positive
  - most sensitive symptom: ankle swelling

**Investigations**
- diagnostic paracentesis
  - 1st aliquot: cell count and differential
  - 2nd aliquot: chemistry (especially albumin, but also total protein; amylase if pancreatitis; TG and chylomicrons if turbid and suspect chylous ascites)
  - 3rd aliquot: C&S, Gram stain
  - 4th aliquot: cytology (usually positive in peritoneal carcinomatosis)

**Treatment**
- diuretic-sensitive ascites
  - Na+ restriction (daily sodium intake <2 g)
  - diuretics: spironolactone, furosemide
  - aim for weight loss 0.5–1 kg/d, more if concomitant peripheral edema (which is mobilized quicker than ascitic fluid); overly rapid weight loss increases risk of renal failure
  - if target weight loss is not achieved and there are no complications, increase dose to achieve target while monitoring for complications
- refractory ascites (diuretics are inadequate or not tolerated)
  - therapeutic paracentesis with intravenous albumin
  - TIPS in an appropriate patient (no contraindications) with potential transplant-free survival advantage
  - liver transplantation should be considered in every case, since development of ascites in patients with cirrhosis is associated with 50% 2 yr mortality
Complication: Primary/Spontaneous Bacterial Peritonitis

- primary/spontaneous bacterial peritonitis (SBP)
  - complicates ascites, but does not cause it (occurs in 10% of cirrhotic ascites); higher risk in patients with GI bleed
  - 1/3 of patients are asymptomatic, thus do not hesitate to do a diagnostic paracentesis in ascites even if no clinical indication of infection
  - fever, chills, abdominal pain, ileus, hypotension, worsening encephalopathy, acute kidney injury
  - Gram-negatives compose 70% of pathogens: *E. coli* (most common), *Streptococcus, Klebsiella*

- diagnosis
  - absolute neutrophil count in peritoneal fluid >0.25x10^9 cells/L (250 cells/mm^3)
  - Gram stain positive in only 10-50% of patients
  - culture positive in <80% of patients (not needed for diagnosis)

- prophylaxis: consider in patients with:
  - cirrhosis or GI bleed: ceftriaxone IV daily or norfloxacin bid x 7 d
  - previous episode of SBP: long-term prophylaxis with daily norfloxacin or TMP-SMX

- treatment
  - IV antibiotics (cefotaxime 2 g IV q8h or ceftriaxone 2 g IV daily is the treatment of choice for 5 d; modify if response inadequate or culture shows resistant organisms)
  - IV albumin (1.5 g/kg at time of diagnosis and 1 g/kg on day 3) decreases mortality by lowering risk of acute renal failure

Biliary Tract

Jaundice

- see Table 2 and Figures 15 and 16

Signs and Symptoms

- dark urine, pale stools: suggests that bilirubin elevation is from direct fraction
- pruritus: suggests chronic disease, cholestasis
- abdominal pain: suggests biliary tract obstruction from stone or pancreatic tumour (obstructive jaundice)
- painless jaundice in the elderly: think of pancreatic cancer, although most patients with pancreatic cancer have pain
- kernicterus: rarely seen in adults due to maturation of blood brain barrier

Investigations

- blood work: CBC, bilirubin (direct and total), liver enzymes (AST, ALT, ALP, GGT), liver function tests (INR/PT, PTT, albumin), amylase
- U/S or CT for evidence of bile duct obstruction (e.g. bile duct dilation)
- direct bile duct visualization
- magnetic resonance cholangiopancreatography (MRCP): non-invasive
- endoscopic ultrasound (EUS): sensitive for stones and pancreatic tumours
- endoscopic retrograde cholangiopancreatography (ERCP): invasive, most accurate, allows for therapeutic intervention
- percutaneous transhepatic cholangiography (PTC): if ERCP fails (endoscopic access not possible)

---

**Figure 15. Approach to jaundice**

**Figure 16. Production and excretion of bilirubin**
Gilbert's Syndrome

Etiology/Epidemiology
- some patients have decreased hepatobiliary uptake
- affects 7% of population, especially males
- autosomal dominant, 70% due to a mutation in the UGT gene

Clinical Features
- presents in teens-20s, often an incidental finding
- only manifestation is intermittent jaundice with increased serum unconjugated bilirubin developing most characteristically while fasting, or at times of acute illness; no other clinical implications

Treatment
- none indicated (entirely benign)

Primary Sclerosing Cholangitis

Definition
- narrowing of biliary tree (intra and/or extrahepatic bile ducts) from scarring

Etiology
- primary/idiopathic (most common)
  - associated with IBD, more commonly UC, in up to 70-80% of patients (usually male) with PSC
- secondary (less common)
  - long-term choledocholithiasis
  - cholangiocarcinoma
  - surgical/traumatic injury (iatrogenic)
  - contiguous inflammatory process
  - post-ERCP
  - associated with HIV/AIDS (“HIV cholangiopathy”)
  - IgG4-related disease

Signs and Symptoms
- often insidious, may present with fatigue and pruritus
- may present with signs of episodic bacterial cholangitis secondary to biliary obstruction

Investigations
- increased ALP (hallmark), less often increased bilirubin
- mildly increased AST, usually <300 U/L
- p-ANCA (30-80%), elevated IgM (40-50%)
- MRCP and ERCP shows narrowing and dilatations of bile ducts that may result in “beading”, both intrahepatic and extrahepatic bile ducts
  - if intrahepatic narrowing only, do anti-mitochondrial antibody to rule out PBC

Complications
- repeated bouts of cholangitis may lead to complete biliary obstruction with resultant secondary biliary cirrhosis and hepatic failure
- increased incidence of cholangiocarcinoma (10-15%): difficult to diagnose and treat

Treatment
- image bile duct (MRCP) at least annually for early detection of cholangiocarcinoma (controversial)
- endoscopic sphincterotomy, biliary stent in selected cases of dominant common bile duct stricture
- antibiotics for cholangitis
- suppurative cholangitis requires emergency drainage of pus in common bile duct
- liver transplantation appears to be the best treatment for advanced sclerosing cholangitis (nearly 90% 1 yr survival; mean follow-up time from diagnosis to need for transplant is 10 yr)
- ursodiol: previously recommended, but studies suggest that at least in high doses it increases mortality

Prognosis
- unfavourable regardless of treatment
- mean survival after diagnosis remains 4-10 yr
Primary Biliary Cholangitis (formerly cirrhosis)

Definition
- chronic inflammation and fibrous obliteration of intrahepatic bile ductules

Etiology/Epidemiology
- likely autoimmune (associated with Sjögren’s syndrome, scleroderma, CREST syndrome, rheumatoid arthritis (RA), thyroiditis)
- affects mainly middle-aged women (M:F = 1:9)

Signs and Symptoms
- often asymptomatic
- initial symptoms: pruritus, fatigue
- chronic: jaundice and melanosi (darkening skin) and other signs of cholestasis
- end-stage: hepatocellular failure, portal HTN, ascites
- high incidence of osteoporosis

Investigations
- increased ALP, GGT; bilirubin rises in later stage
- positive anti-mitochondrial antibodies (AMA; 95% specificity and sensitivity)
- elevated IgM
- increased serum cholesterol (mild increase in LDL, larger increase in HDL)
- may have: xanthelasmas, xanthomas
- liver biopsy confirms diagnosis and stages severity
- normal bile duct on MRCP rules out bile duct obstruction which can mimic PBC
- recently described “overlap” syndromes with autoimmune cholangitis, autoimmune hepatitis, sclerosing cholangitis

Treatment
- drugs that treat the underlying disease:
  - ursodiol (usual first line treatment)
  - obeticholic acid (particularly if inadequate response to ursodiol)
  - cholestyramine (for pruritus and hypercholesterolemia)
  - calcium and vitamin D for low bone density; bisphosphonates if osteoporosis severe
  - monitor for thyroid disease
  - liver transplant if disease severe, progressive

Prognosis
- can be fatal, although not all asymptomatic patients show progression

Biliary Colic, Cholecystitis

- see General Surgery, GS52

Ascending Cholangitis

- see General Surgery, GS54

Definition
- infection of the biliary tree

Etiology
- stasis in the biliary tract due to obstruction or stricture (usually from previous cholecystectomy)
- infection originates in the duodenum or spreads hematogenously from the portal vein
- bacteria
  - E. coli, Klebsiella, Enterobacter, Enterococcus
  - co-infection with Bacteroides and Clostridium can occur
### Signs and Symptoms
- Charcot’s triad: fever, RUQ pain, jaundice (50-70%)
- Reynolds’ pentad in patients with suppurative cholangitis: fever, RUQ pain, jaundice, hypotension, altered mental status

### Investigations
- increased WBC
- usually increased ALP and bilirubin, ALT variably elevated
- blood culture
- abdominal U/S: CBD dilation, stones

### Treatment
- most important is drainage, ideally via ERCP; perform by percutaneous biliary or by surgical routes (least often) if ERCP not possible
- antibiotic therapy: broad spectrum to cover Gram-negatives, *Enterococcus*, and anaerobes (especially if CBD manipulation); no clear consensus on antibiotic choice but consider:
  - ampicillin + sulbactam or piperacillin/tazobactam
  - metronidazole + 3rd generation cephalosporin (e.g. ceftriaxone) or fluoroquinolone (e.g. ciprofloxacin or levofloxacin)
  - carbapenem monotherapy (e.g. imipenem or meropenem)

### Prognosis
- good with effective drainage and antibiotics in mild to moderate cases
- high mortality (~50%) in patients with Reynolds pentad

### Pancreatic Enzyme Abnormalities

#### Causes of Increased Serum Amylase
- pancreatic disease
  - pancreatitis, pancreatic duct obstruction (e.g. ampullary cancer), pseudocyst, abscess, ascites, trauma, cancer
- non-pancreatic abdominal disease
  - biliary tract disease, bowel obstruction/ischemia, perforated or penetrating ulcer, ruptured ectopic pregnancy, aneurysm, chronic liver disease, peritonitis
- non-abdominal disease
  - cancer (lung, ovary, esophagus, etc.), salivary gland lesions, bulimia, renal transplant/insufficiency, burns, ketoacidosis
  - macroamylasemia

#### Causes of Increased Serum Lipase
- pancreatic disease: same as above
- non-pancreatic abdominal disease (mild elevations only): same as above
- non-abdominal disease
  - macrolipasemia
  - renal failure

### Acute Pancreatitis

#### Etiology (most common are alcohol and gallstones)
- Idiopathic: thought to be hypertensive sphincter or microthlitiasis
  - Gallstones (45%)
  - Ethanol (35%)
- Tumours: pancreas, ampulla, choledochecoele
- Scorpion stings
- Microbiological
  - viral: mumps, rubella, varicella, viral hepatitis, CMV, EBV, HIV, Coxsackie virus, echovirus, adenovirus
  - parasites: ascariasis, clonorchiasis, echinococciosis
- Autoimmune: SLE, *polyarteritis nodosa* (PAN), Crohn’s disease
- Surgery/trauma
  - manipulation of sphincter of Oddi (e.g. ERCP), post-cardiac surgery, blunt trauma to abdomen, penetrating peptic ulcer
- Hyperlipidemia (TG >11.3 mmol/L; >1000 mg/dL), hypercalcemia, hypothermia
- Emboli or ischemia
- Drugs/toxins
  - azathioprine, mercaptopurine, furosemide, estrogens, methyl dopa, H2-blockers, valproic acid, antibiotics, acetaminophen, salicylates, methanol, organophosphates, steroids (controversial)
Pathophysiology
- activation of proteolytic enzymes within pancreatic cells, starting with trypsin, leading to local and systemic inflammatory response
- in gallstone pancreatitis, this is due to mechanical obstruction of the pancreatic duct by stones
- in ethanol-related pancreatitis, pathogenesis is unknown
- in rare genetic diseases, mutations prevent the physiological breakdown of trypsin required normally to stop proteolysis (e.g. mutant trypsin in hereditary pancreatitis or mutation in SPINK 1 gene, which normally inhibits activated trypsin); may be model for ethanol-related pancreatitis

Pathology
- mild (interstitial)
  - peri-pancreatic fat necrosis
  - interstitial edema
- severe (necrotic)
  - extensive peri-pancreatic and intra-pancreatic fat necrosis
  - parenchymal necrosis and hemorrhage → infection in 60%
  - release of toxic factors into systemic circulation and peritoneal space (causes multi-organ failure)
- severity of clinical features may not always correlate with pathology
- 3 phases
  - local inflammation + necrosis → hypovolemia
  - systemic inflammation in multiple organs, especially in lungs, usually after IV fluids given → pulmonary edema
  - local complications 2 wk after presentation → pancreatic sepsis/abscess

Signs and Symptoms
- pain: epigastric, noncolicky, constant
- jaundice: compression or obstruction of bile duct
- may radiate to back
- may improve when leaning forward (Inglefinger’s sign)
- tetany: transient hypocalcemia
- tender rigid abdomen; guarding
- nausea/vomiting
- abdominal distention from paralytic ileus
- fever: chemical, not due to infection
- hypovolemic shock: can lead to renal failure
- acute respiratory distress syndrome
- coma

Investigations
- increased serum pancreatic enzymes: amylase, lipase (more specific)
- ALT >150 specific for biliary cause
- increased WBC, glucose, low calcium
- imaging: CT most useful for diagnosis and prognosis
  - x-ray: “sentinel loop” (dilated proximal jejunum), calcification, and “colon cut-off sign” (colonic spasm)
  - U/S: useful for evaluating biliary tree (67% sensitivity, 100% specificity)
  - CT scan with IV contrast: useful for diagnosis and prognosis because contrast seen only in viable pancreatic tissue, non-viable areas can be biopsied percutaneously to differentiate sterile from infected necrosis
  - ERCP or MRCP if cause uncertain, assess for duct stone, pancreatic or ampullary tumour, pancreas divisum

Classification
- interstitial edematous vs. necrotizing
- mild, moderate, severe

Prognosis
- usually a benign, self-limiting course, single or recurrent
- occasionally severe leading to:
  - shock
  - pulmonary edema
  - multi-organ dysfunction syndrome
  - GI ulceration due to stress
  - death
  - numerous scales to describe severity; probably most useful is proportion of pancreas not taking up contrast on CT done 48 h after presentation (necrotic pancreas does not take up the contrast dye)
  - presence of organ failure, particularly organ failure that persists >48 h, is associated with worse outcomes

Table 24. Collections in Pancreatitis (Revised 2012 Atlanta Classification)

<table>
<thead>
<tr>
<th></th>
<th>Liquid</th>
<th>Solid</th>
</tr>
</thead>
<tbody>
<tr>
<td>Acute</td>
<td>Acute peripancreatic fluid collection (APFC)</td>
<td>Acute necrotic collection (ANC)</td>
</tr>
<tr>
<td>Chronic</td>
<td>Pancreatic pseudocyst</td>
<td>Walled-off necrosis (WON)</td>
</tr>
</tbody>
</table>

All of these collections are classified as infected or not infected
**Treatment**
- Goals (only supportive therapy available)
  1. Hemodynamic stability
  2. Analgesia
  3. Oxygen
  4. Stop progression of damage (difficult)
  5. Treat local and systemic complications
- Antibiotics controversial except in documented infection (use cephalosporins, imipenem)
- Aspiration of necrotic areas of pancreas to diagnose infection; drain if infected
- IV fluids (crystalloid or colloid)
- Beware third spacing of fluid, monitor urine output carefully
- NG suction (lets pancreas rest) if vomiting, stomach very distal
- Endoscopic sphincterotomy if severe gallstone pancreatitis (i.e. cholangitis or ongoing obstruction)
- Nutritional support: nasojejunal feeding tube or TPN if cannot tolerate enteric feeds
- Recent evidence supports nasogastric enteral (or oral if feasible) feeds
- No benefit: glucagon, atropine, aprotinin, H2-blockers, peritoneal lavage
- Follow clinically and CT/ultrasound to exclude complications
- No benefit: DM, pancreatic duct damage
- Splenic and portal vein thrombosis: no effective therapy described, anticoagulation not proven,
- Bleeding: (1) gastric varices if splenic vein thrombosis, (2) pseudoaneurysm of vessels in areas of
  necrosis, especially splenic artery, (3) duodenal ulcer related to compression of duodenum by enlarged
  pancreas
- Splenic and portal vein thrombosis: no effective therapy described, anticoagulation not proven,
- Hazardous
- Rare: DM, pancreatic duct damage

**Late Complications**
- Pseudocysts: follow if asymptomatic, drain if symptomatic or growing
- Drain: choice of endoscopic, percutaneous under radiological guidance, or surgical
- Infected necrosis/abscesses: antibiotics + percutaneous drainage, endoscopic vs. surgical
- Bleeding: (1) gastric varices if splenic vein thrombosis, (2) pseudoaneurysm of vessels in areas of
  necrosis, especially splenic artery, (3) duodenal ulcer related to compression of duodenum by enlarged
  pancreas
- Splenic and portal vein thrombosis: no effective therapy described, anticoagulation not proven,
- Hazardous
- Rare: DM, pancreatic duct damage

**Chronic Pancreatitis**

**Definition**
- Irreversible damage to pancreas characterized by
  1. Pancreatic cell loss (from necrosis)
  2. Inflammation
  3. Fibrosis

**Etiology/Pathophysiology**
- Alcohol (most common)
  - Causes a larger proportion (>90%) of chronic pancreatitis than acute pancreatitis
  - Changes composition of pancreatic juice (e.g. increases viscosity)
  - Decreases pancreatic secretion of pancreatic stone protein (lithostathine), which normally solubilizes
    calcium salts
  - Precipitation of calcium within pancreatic duct results in duct and gland destruction
  - Toxic effect on acinar and duct cells – directly or via increasing free radicals
  - Acinar cell injury leads to cytokine release, which stimulates pancreatic stellate cells to form collagen
    (leading to fibrosis)
  - Varying degrees of ductular dilatation, strictures, protein plugs, calcification
  - No satisfactory theory to explain why only a minority of individuals with alcohol use disorder
    develop pancreatitis
  - Unusual causes
    - Cystic fibrosis
    - Severe protein-calorie malnutrition
    - Hereditary
    - Idiopathic

**Signs and Symptoms**
- Early stages
  - Recurrent attacks of severe abdominal pain (upper abdomen and back)
  - Chronic painless pancreatitis: 10%
- Late stages: occurs in 15% of patients
  - Steatorrhea (maldigestion) when >90% of function is lost
  - Diabetes, calcification, jaundice, weight loss, pseudocyst, ascites, GI bleed

**Prophylactic Antibiotics Cannot Reduce Infected Pancreatic Necrosis and Mortality in Acute Necrotizing Pancreatitis: Evidence from a Meta-Analysis of Randomized Controlled Trials**

**Purpose:** To review the effectiveness of IV antibiotics on pancreatic necrosis.

**Study Selection:** RCTs comparing antibiotics with placebo or no treatment.

**Results:** Seven trials (n=467) were included. Antibiotics were not statistically superior to controls in reduction of infected necrosis and mortality.

**Conclusion:** Prophylactic antibiotics cannot reduce infected pancreatic necrosis and mortality in patients with acute necrotizing pancreatitis.

**Note:** In practice, the temptation to give antibiotics for pancreatitis is mainly in the setting of a sick patient with fever and suggestive pancreatic necrosis on CT scan. It is difficult to determine whether pancreatic necrosis has become infected without aspiration biopsy (see Curr Gastroenterol Rep 2009;11:104-110).
Investigations
- laboratory
  - increase in serum glucose
  - increase in serum ALP, less commonly bilirubin (jaundice)
  - serum amylase and lipase usually normal
  - stool elastase is low in steatorrhea
- abdominal X-ray: pancreatic calcifications
- U/S or CT: calcification, dilated pancreatic ducts, pseudocyst
- MRCP or ERCP: abnormalities of pancreatic ducts-narrowing and dilatation
- EUS: abnormalities of pancreatic parenchyma and pancreatic ducts, most sensitive test
- 72 h fecal fat test: measures exocrine function
- secretin test: gold standard, measures exocrine function but difficult to perform, unpleasant for patient, expensive
- fecal pancreatic enzyme measurement (elastase-1, chymotrypsin): available only in selected centres

Treatment
- most common problem is pain, difficult to control
- general management
  - complete abstinence from alcohol
  - enzyme replacement may help pain by resting pancreas via negative feedback
  - analgesics
  - celiac ganglion blocks
  - time: pain decreases with time as pancreas “burns out”
- endoscopy: sphincterotomy, stent if duct dilated, remove stones from pancreatic duct
- surgery: drain pancreatic duct (pancreaticojejunostomy) if duct dilated (more effective than endoscopy); resect pancreas if duct contracted
- steatorrhea
  - pancreatic enzyme replacement
  - restrict fat, increase carbohydrate and protein (may also decrease pain)
  - neither endoscopy nor surgery can improve pancreatic function

Autoimmune Pancreatitis
- most commonly presents as a mimicker of pancreatic cancer (pancreatic mass detected because of jaundice ± abdominal pain)

Investigations
- histology: lymphocyte and plasma cell infiltration of pancreas
- imaging: focal or diffuse enlargement of pancreas on CT or MRI, sausage shaped, low density rim around pancreas
- serology: increased serum IgG4
- other organ involvement: sialadenitis, retroperitoneal fibrosis, biliary duct narrowing, nephritis

Treatment
- responds to prednisone

Clinical Nutrition

Determination of Nutritional Status

Challenging to differentiate markers of malnutrition from markers of disease
- most important feature in assessing the need for nutritional support is weight loss (expressed as change body mass index [kg/m²])
- Subjective Global Assessment divides nutritional status into A) adequately nourished, B) mild or moderate malnutrition and C) severe malnutrition in order to identify those who will benefit from nutritional support
- includes weight change in past 6 mo, weight change in past 2 weeks, dietary intake change, current dietary intake, GI symptoms, functional capacity, effect of disease on nutritional requirements and physical examination, including loss of subcutaneous fat/muscles wasting/edema/ascites

Determining Nutritional Requirements

- calories: total energy expenditure (TEE) = resting energy expenditure (REE) X stress factor (eg 1.7 for burns) usually works out to be 25-35 kcal/kg depending on how disease affects metabolism, with intravenous nutrition delivered as about 60% carbohydrate, 40% fat. Current trend is to provide fewer calories ("permissive underfeeding"), especially in ICU, to prevent hyperglycemia
- protein: 1-2 g/kg/d, depending on effect of disease on protein metabolism. In disease a greater proportion of energy expenditure comes from protein than in health
- electrolytes, minerals and vitamins also required

Indications for Aggressive Nutritional Support:
- inability to meet nutritional needs; logical, but convincing evidence from literature not available for ICU and other acute illnesses
- evidence that nutritional support improves outcome available for short bowel syndrome (home TPN), when provided before major abdominal or thoracic surgery if there is substantial malnutrition, before radiation therapy for cancer of esophagus, head and neck, decompensated alcoholic liver disease, pancreatitis (acute and chronic)
- nutritional support at best prevents protein loss but usually no gain

Enteral Nutrition

Definition
- enteral nutrition (tube feeding) is a way of providing food through a tube placed in the stomach or the small intestine
- nasogastric (NG), or nasojejunal (NJ) if nutritional support required for brief time; percutaneous endoscopic gastrostomy ("G-tube" or "PEG tube")/percutaneous endoscopic jejunostomy (J-tube) if nutrition support required for more than 1 mo
- tubes can also be placed endoscopically, radiologically or surgically

Indications
- oral feeding inadequate or contraindicated

Feeds
- polymeric feeds contain whole protein, carbohydrate, fat as a liquid, with or without fibre
- elemental feeds contain protein as amino acids, carbohydrate as simple sugars, fat content low (therefore high osmolarity)
- specific diets: low carbohydrate/high fat solution for ventilated patients (carbohydrate has a high respiratory quotient so minimizes carbon dioxide production), high energy, low electrolyte solutions for dialysis patients

Relative Contraindications
- non-functioning gut (e.g. intestinal obstruction, enterocutaneous fistulae)
- uncontrolled diarrhea
- GI bleeding

Complications
- aspiration
- diarrhea
- refeeding syndrome (rare): carbohydrate can stimulate excessive insulin release, leading to cellular uptake and low serum levels of phosphate, magnesium, potassium
- overfeeding syndrome (rare): hypertonic dehydration, hyperglycemia, hypercapnea, azotemia (from excess protein)

Parenteral Nutrition

Definition
- parenteral nutrition (PN) is the practice of feeding a person intravenously, bypassing the usual process of eating and digestion

Indications
- short-term (<1 mo)
  - use whenever GI tract not functioning
  - only situations where PN has been well shown to increase survival are after bone marrow transplant and in short bowel syndrome, some evidence for benefit in gastric cancer, but often used in ICU, perioperatively, and in difficult-to-control sepsis
  - pre-operative: only useful in severely malnourished (e.g. loss of >15% of pre-morbid weight, serum albumin <28 g/L or <2.8 g/dL), and only if given for ≥2 wk
  - renal failure: PN shown to increase rate of recovery; no increase in survival
  - liver disease: branched chain amino acids may shorten duration of encephalopathy; no increase in survival
  - IBD: PN closes fistulae and heals acute exacerbations of mucosal inflammation, but effect is transient (EN is equally effective)

Most Common Indications for Artificial Nutrition Support
- Preexisting nutritional deprivation
- Anticipated or actual inadequate energy intake by mouth
- Significant multiorgan system disease

Whenever possible, enteral nutrition is ALWAYS preferable over parenteral nutrition
• some evidence for efficacy, but convincing data not available for:
  • radiation/chemotherapy-induced enteritis
  • AIDS with wasting diarrhea
  • severe acute pancreatitis
• long-term (>1 mo): can be given at home
  • severe untreated small bowel disease (e.g. radiation enteritis, extensive CD, high output fistulae)
  • following surgical resection of >70% of small bowel (e.g. small bowel infarction)
  • severe motility diseases (e.g. scleroderma affecting bowel)

Relative Contraindications
• functional GI tract for enteral nutrition
• active infection; at least until appropriate antibiotic coverage
• inadequate venous access; triple-lumen central venous lines usually prevent this problem

Complications of PN
• sepsis: most serious of the common complications
• mechanical pneumothorax from insertion of central line, catheter migration and thrombosis, air embolus
• metabolic: congestive heart failure, hyperglycemia, gallstones, cholestasis

Enteral Nutrition vs. Parenteral Nutrition
• metabolic: congestive heart failure, hyperglycemia, gallstones, cholestasis
• mechanical: pneumothorax from insertion of central line, catheter migration and thrombosis, air embolus
• sepsis: most serious of the common complications
• inadequate venous access; triple-lumen central venous lines usually prevent this problem
• active infection; at least until appropriate antibiotic coverage

**Figure 1. Abdominal incisions**

**Lateral Abdominal Wall Layers and their Continuous Spermatic and Scrotal Structures (superficial to deep)**
1. skin (epidermis, dermis, subcutaneous fat)
2. superficial fascia
   - Camper’s fascia (fatty) → Dartos muscle/fascia
   - Scarpa’s fascia (membranous) → Colles’ superficial perineal fascia
3. muscle (see Figure 2 and Figure 3)
   - external oblique → inguinal ligament → external spermatic fascia and fascia lata
   - internal oblique → cremasteric muscle/fascia
   - transversus abdominis → posterior inguinal wall
4. transversalis fascia → internal spermatic fascia
5. preperitoneal fat
6. peritoneum → tunica vaginalis

**Midline Abdominal Wall Layers (superficial to deep)**
1. skin
2. superficial fascia
3. rectus abdominis muscle: in rectus sheath, divided by linea alba (see Figure 3)
   - above arcuate line (midway between symphysis pubis and umbilicus)
     - anterior rectus sheath = external oblique aponeurosis and anterior leaf of internal oblique aponeurosis
     - posterior rectus sheath = posterior leaf of internal oblique aponeurosis and transversus abdominis aponeurosis
   - below arcuate line
     - aponeuroses of external oblique, internal oblique, transversus abdominis all pass in front of rectus abdominis
4. arteries: superior epigastric (branch of internal thoracic), inferior epigastric (branch of external iliac); both arteries anastomose and lie behind the rectus muscle (superficial to posterior rectus sheath above arcuate line)
5. transversalis fascia
6. peritoneum

Differential Diagnoses of Common Presentations

## Acute Abdominal Pain

- *Acute abdomen* = severe abdominal pain of acute onset and requires urgent medical attention.
- In patients with acute abdominal pain, the first diagnoses that you should consider are those requiring potential urgent surgical intervention.
- Two main patterns constituting urgent general surgery referrals are peritonitis and obstruction.

### Table 1. Differential Diagnosis of Acute Abdominal Pain

### Localization of Pain

Most digestive tract pain is perceived in the midline because of bilaterally symmetric innervation; kidney, ureter, ovary, or somatically innervated structures are more likely to cause lateralized pain.

Parietal peritoneal: supplied by somatic sensory nerves of body wall. Pain is sharp and well-localized.

Visceral peritoneal: supplied by autonomic sensory fibres. Pain is colicky and poorly-localized.

Abdominal Mass

*Indicated need for urgent surgical evaluation

Pancreatitis can look like a surgical abdomen, but is rarely an indication for immediate surgical intervention
Gastrointestinal Bleeding

- see Gastroenterology, G25

Indications for Surgery
- failure of medical management
- exsanguinating hemorrhage; hemodynamic instability despite vigorous resuscitation
- recurrent hemorrhage with up to two attempts of endoscopic hemostasis
- prolonged bleeding with transfusion requirement >3 units
- bleeding at rate >1 unit/8 h

Surgical Management of GI Bleeding
- UGIB
  - bleeding from a source proximal to the ligament of Treitz
  - often presents with hematemesis and melena unless very brisk (then can present with hematochezia)
  - initial management with endoscopy; if fails, then consider surgical management appropriate to etiology
  - PUD accounts for approximately 55% of severe UGIB
- LGIB
  - bleeding from a source distal to the ligament of Treitz
  - often presents with BRBPR unless proximal to transverse colon
  - may occasionally present with melena
  - initial management with colonoscopy to detect and potentially stop source of bleeding
  - 75% of patients will spontaneously stop bleeding, however if bleeding continues barium enema should NOT be performed
  - angiography or RBC scan to determine source as indicated
  - surgery indicated if bleeding is persistent - aimed at resection of area containing source of bleeding
  - obscure bleed may require blind total colectomy if the source is not found

*Managed surgically in most cases

Jaundice

- see Gastroenterology, G43
Pre-Operative Preparations

Considerations
- informed consent (see Ethical, Legal, and Organizational Medicine, ELM7)
- screening questionnaire to determine risk factors e.g. age, exercise capacity, medication use, allergies
- consider pre-operative anesthesia, medicine consult as indicated to optimize patient status
- NPO according to fasting guidelines (see Anesthesia and Perioperative Medicine, A6)
- IV – balanced crystalloid at maintenance rate (4:2:1 rule for pediatrics, roughly 100-125 cc/h for adults): normal saline or Ringer's lactate (RL most common); bolus to catch up on estimated losses including losses from bowel prep
- appropriate use of fluids perioperatively decreases risk of cardiorespiratory complications
- patient's regular medications included with the exception of hypoglycemic agents, diuretics and ACEI
- patients on steroids may require stress dose coverage
- anticoagulation/antiplaetelet medication must be managed to decrease surgical bleeding but not put patient at risk for increased thrombotic events (e.g. Bridging: switching from warfarin to LMWH, easier to start/stop as needed)
- prophylactic antibiotics depending on wound class (immediately/within 1 h prior to incision): cefazolin (Ancef®) ± metronidazole (Flagyl®) for contaminated cases
- role of MBP. Current evidence suggests that use of MBP pre-operatively has no impact on post-operative complications and therefore routine use of MBP for non-LAR elective colorectal surgery is not recommended
  - MBP is still frequently used for left-sided colonic surgery (i.e. sigmoid and rectum) to facilitate bowel manipulation and colorectal anastomoses
  - consider VTE prophylaxis for all inpatient surgery (LMWH or heparin)
  - only hold VTE prophylaxis if epidural is expected
  - smoking cessation and weight loss pre-operatively can significantly decrease post-operative complications
- infection: delay elective surgery until infection controlled, including respiratory infection (particularly in asthma patients)

Investigations
- see Anesthesia and Perioperative Medicine, A2
- routine pre-operative laboratory investigations for elective procedures should be selective
  - only ASA class and surgical risk have been found to independently predict post-operative adverse effects
- blood components: group and screen or cross and type depending on procedure
- CBC, electrolytes, creatinine
- INR/PT, PTT
- CXR (PA and lateral) for patients with history of cardiac or pulmonary disease
- ECG as indicated by history or if >69 yr and no risk factors
- β-hCG testing in all women of reproductive age

Drains
- NGT
  - indications: gastric decompression, analysis of gastric contents, irradiation/dilution of gastric contents, feeding, if necessary
  - 2 types: NGT (for drainage or feeding) and Dobhoff (for feeding only)
  - insertion should be done in stages with x-ray protocol to avoid injury
  - contraindications: suspected basilar skull fracture, obstruction of nasal passages, esophageal stricture, esophageal varices
- Foley catheter with urometer
  - indications: to accurately monitor urine output, decompression of bladder, relieve obstruction, rapidly expanding suprapubic mass
  - contraindications: suspected urethral injury, and difficult insertion of catheter

Surgical Complications
- general principles in preventing complications during the post-operative period include:
  - frequent examination of the patient (daily or more) and their wound
  - removal of surgical tubes as soon as possible (e.g. Foley catheters and surgical drains)
  - early ambulation
  - monitor fluid balance and electrolytes
  - analgesia - enough to adequately address pain, but not excessive (minimize opioids)
  - skillful nursing care

Post-Operative Fever
- fever does not necessarily imply infection particularly in the first 24-48 h post-operative
- fever may not be present or is blunted if patient is receiving chemotherapy, glucocorticoids, or other immunosuppression
**Wound/Incisional Complications**

**WOUND CARE** (see Plastic Surgery, PL8)
- can shower POD #2-3 after epithelialization of wound (or earlier depending on dressing)
- dressings can be removed POD #2 and left uncovered if dry
- examine wound if wet dressing, signs of infection (fever, tachycardia, and pain)
- skin sutures and staples can be removed POD #7-10
  - exceptions: incision crosses crease (groin), closed under tension, in extremities (hand) or patient factors (elderly, corticosteroid use, or immunosuppressed) removed POD #14, earlier if signs of infection
- negative pressure dressings consist of foam and suction, promote granulation
  - ideal for large (grafted sites) or non-healing wounds (irradiated skin, or ulcer)

**DRAINS**
- drains may be placed selectively at the time of surgery to prevent fluid accumulation (blood, pus, serum, bile, and urine)
  - can be used to assess quantity of third space fluid accumulation post-operatively
- potential route of infection: to decrease risk of wound infection bring out through separate incision (vs. operative wound) and remove as soon as possible
- types of drains
  - open (e.g. Penrose), higher risk of infection
  - closed: 1) Gravity drainage (e.g. Foley catheter); 2) Underwater-seal drainage system (e.g. chest tube); 3) Suction drainage (e.g. Jackson-Pratt)
  - sump (e.g. NGT)
  - monitor drain outputs daily
  - drains should be removed once drainage is minimal (usually <30-50 cc/24 h)
  - drains do not guarantee that the patient will not form a collection of fluid
  - ridged drains can erode through internal structures, and excessive suction can cause necrosis
  - evidence does not support routine post-operative drainage of abdominal cavity

**SURGICAL SITE INFECTION**

**Etiology**
- S. aureus, E. coli, Enterococcus, Streptococcus spp., Clostridium spp.

**Risk Factors**

**Table 4. Procedures and Their Impact on Surgical Site Infection**

<table>
<thead>
<tr>
<th>Classification</th>
<th>Clean</th>
<th>Clean-Contaminated</th>
<th>Contaminated</th>
<th>Dirty/Infected</th>
</tr>
</thead>
<tbody>
<tr>
<td>Definition</td>
<td>Incision under sterile conditions; nontraumatic; no entrance of hollow organ</td>
<td>Incision under sterile conditions; ENTRANCE of hollow viscous; no evidence of active infection; minimal contamination</td>
<td>Incision under sterile conditions; MAJOR contamination of wound during procedure (i.e. gross spillage of stool, infection in biliary, respiratory, or GU systems)</td>
<td>Established infection present before wound is made in skin</td>
</tr>
<tr>
<td>Example</td>
<td>Hernia repair</td>
<td>Routine cholecystectomy; colon resection</td>

<td>3.4%</td>
<td>7-10%</td>
<td>30-40%</td>
</tr>
<tr>
<td>Wound Closure</td>
<td>Primary closure</td>
<td>Primary closure</td>
<td>Often secondary closure</td>
<td>Secondary closure</td>
</tr>
</tbody>
</table>
- patient characteristics
  - age, DM, steroids, immunosuppression, obesity, burn, malnutrition, patient with other infections, traumatic wound, radiation, and chemotherapy
- other factors
  - prolonged pre-operative hospitalization, reduced blood flow, break in sterile technique, multiple antibiotics, hematoma, seroma, foreign bodies (drains, sutures, grafts), skin preparation, hypoxemia, and hypothermia

Prophylaxis
- pre-operative antibiotics for most surgeries (cefazolin ± metronidazole or if β-lactam allergy, clindamycin ± gentamycin)
  - within 1 h pre-incision; can redose at 1-2 half-lives (~q4-8h) in the OR
  - not required for low risk elective thyroidectomy, cholecystectomy, hemorrhoidectomy, fistulotomy, and sphincterotomy for fissure
- some evidence suggests role in breast surgery
- reserve post-operative antibiotics for treatment of suspected or documented intra-abdominal infection
- normothermia (maintain patient temperature 36-38°C during OR)
- hyperoxygenation (consider FiO2 of 80% in OR)
- chlorhexidine-alcohol wash of surgical site
- hair removal should not be performed unless necessary; if so, clipping superior to shaving
- local: technical failure of closure, technical errors including excessive tension on the wound, increased Risk Factors

WOUND DEHISCENCE
- if significant may need to re-operate
- use sterile closing tray for laparotomy

Clinical Feature
- typically fever POD #5-8 (Streptococcus and Clostridium can present in 24 h)
- localized pain, blanchable erythema, induration, purulent discharge, and warmth
- complications: fistula, sinus tracts, sepsis, abscess, suppressed wound healing, superinfection, spreading infection to myonecrosis or fascial necrosis (necrotizing fasciitis), wound dehiscence, evisceration, and hernia

Treatment
- examination of the wound: inspect, compress adjacent areas, swab drainage for C&S and Gram stain
- re-open affected part of incision, drain, pack, heal by secondary intention in most cases
- for deeper or necrotizing infections, debride necrotic and non-viable tissue
- antibiotics and demarcation of erythema only if cellulitis or immunodeficiency

WOUND HEMORRHAGE/HEMATOMA

Risk Factors
- anticoagulant therapy, coagulopathies, thrombocytopenia, DIC, severe liver disease, myeloproliferative disorders, severe arterial HTN, and severe cough
- more common with transverse incisions through muscle, due to cutting of muscle
- more clinically relevant in small working spaces such as breast surgery or thyroid surgery

Clinical Features
- pain, swelling, discolouration of wound edges, and leakage
- rapidly expanding neck hematoma can compromise airway and is a surgical emergency: consider having a suture kit at bedside in all neck surgery in the event of having to open the wound emergently (most important treatment in this case is to protect the airway with intubation)

Treatment
- pressure dressing
- open drainage ± wound packing (large hematoma only)
- if significant bleeding, may need to re-operate to find source (often do not find a discrete source)

SEROMA
- fluid collection other than pus or blood
- secondary to transection of lymph vessels
- delays healing
- increased infection risk if drained

Treatment
- observation
- consider pressure dressing ± needle drainage (this may increase infection risk)
- if significant may need to re-operate

WOUND DEHISCENCE
- disruption of a wound that was primarily closed, causing loss of barrier of skin or fascia

Risk Factors
- local: technical failure of closure, technical errors including excessive tension on the wound, increased intra-abdominal pressure (e.g. COPD, ileus, bowel obstruction), hematoma, infection, poor blood supply, radiation, patient not fully paralyzed while closing, and transverse incision

Surgical Complications

- Systemic: male, smoking, malnutrition (hypalbuminemia, vitamin C deficiency), connective tissue diseases, immunosuppression, pulmonary disease, ascites, poor nutrition, steroids, chemotherapy, obesity, and other (e.g. age, sepsis, and uremia)
- DM alone is not a risk factor

Clinical Features
- Typically POD #1-3 or #7-10; most common presentation sign is serosanguinous drainage from wound
- ± evisceration
- Palpation of wound edge: should normally feel a "healing ridge" from abdominal wall closure (raised area of tissue under incision)

Treatment
- Place moist dressing over wound with binder around abdomen and transfer to OR
- May consider conservative management with debridement of fascial and/or skin margins
- Evisceration (i.e. "burst abdomen") is a surgical emergency: take patient for operative re-closure without abdomen binder

Incisional Hernia
- Defined as either part or all of an abdominal wound in which the fascial edges have separated
- Symptoms aggravated by coughing or straining
- Smaller fascial defects such as laparoscopic port sites have a higher risk of incarceration
- Definitive treatment: surgical repair
  - Large hernias that pose little risk of incarceration do not need to be repaired

Urinary and Renal Complications

Urinary Retention
- May occur after any operation with general anesthesia or more commonly with spinal anesthesia
- More likely in older males with history of benign prostatic hyperplasia, and patients on anticholinergics

Clinical Feature
- Abdominal discomfort, palpable bladder, overflow incontinence, post-void residual urine volume >100 mL

Treatment
- Foley catheter to rest bladder, then trial of voiding
- Often accompanied by an alpha-blocker such as tamsulosin

Oliguria/Anuria

Etiology
- Prerenal vs. renal vs. postrenal
- Most common post-operative cause is prerenal ± ischemic ATN
  - External fluid loss: hemorrhage, dehydration, and diarrhea
  - Internal fluid loss: third-spacing due to bowel obstruction, and pancreatitis

Clinical Feature
- Urine output <0.5 cc/kg/h, increasing Cr, and increasing BUN

Treatment
- According to underlying cause; fluid deficit is treated with crystalloid (NS or RL)

Post-Operative Dyspnea

See Respiratory Complications and Cardiac Complications, GS12

Etiology
- Respiratory: atelectasis, pneumonia/pneumonitis, pulmonary embolus (PE), ARDS, asthma, and pleural effusion
- Cardiac: MI, arrhythmia, and CHF
- Inadequate pain control

Respiratory Complications

Atelectasis
- Comprises 90% of post-operative pulmonary complications

Risk Factors
- COPD, smoking, obesity, and elderly persons
- Upper abdominal/thoracic surgery, oversedation, significant post-operative pain, and poor inspiratory effort
Clinical Features
- low-grade fever on POD #1, tachycardia, crackles, decreased breath sounds, bronchial breathing, and tachypnea

Treatment
- pre-operative prophylaxis
  - smoking cessation (best if >8 wk pre-operative)
- post-operative prophylaxis
  - incentive spirometry, deep breathing exercise, chest physiotherapy, and intermittent positive-pressure breathing
  - selective NGT decompression after abdominal surgery
  - short-acting neuromuscular blocking agents
  - minimize use of respiratory depressant drugs, appropriate pain control, and early ambulation

PNEUMONIA/PNEUMONITIS
- may be secondary to aspiration of gastric contents during anesthetic induction or extubation, causing a chemical pneumonitis

Risk Factors
- aspiration: general anesthetic, decreased LOC, GERD, full stomach, bowel/gastric outlet obstruction + non-functioning NGT, pregnancy, and seizure disorder
- non-aspiration: atelectasis, immobility, and pre-existing respiratory disease

Clinical Features
- productive cough, and fever
- tachycardia, cyanosis, respiratory failure, and decreased LOC
- CXR: pulmonary infiltrate

Treatment
- prophylaxis: see atelectasis prophylaxis, pre-operative NPO/NGT, and rapid sequence anesthetic induction
- immediate removal of debris and fluid from airway
- consider endotracheal intubation and flexible bronchoscopic aspiration
- empiric IV antibiotics to cover oral nosocomial aerobes and anaerobes (e.g. piperacillin-tazobactam, cefepime-tometronidazole)

PULMONARY EMBOLUS

Clinical Features
- unilateral leg swelling and pain (DVT as a source of PE), sudden onset dyspnea, pleuritic chest pain, tachycardia, and fever
- most commonly POD #8-10, but can occur anytime post-operatively, even after discharge
- diagnosis made by Chest CT scan usually

Treatment
- initial treatment: IV heparin or subcutaneous LMWH, bridging to therapeutic anticoagulation is required for a minimum of 3 mo (usually 6 mo); for patients with cancer, or other risk factors for hypercoagulability, the duration of anticoagulation may be longer
- Greenfield (IVC) filter if contraindications to anticoagulation helps prevent worsening of PE
- prophylaxis: subcutaneous heparin (5000 U bid) or LMWH, compression stockings (TED™ Hose), and sequential compression devices

PULMONARY EDEMA

Etiology
- cardiogenic vs. noncardiogenic
- circulatory overload: excess volume replacement, LV failure, shift of fluid from peripheral to pulmonary vascular bed, negative airway pressure, and alveolar injury due to toxins (e.g. ARDS)
- more common with pre-existing cardiac disease
- negative pressure pulmonary edema due to inspiratory efforts against a closed glottis upon awakening from general anesthesia

Clinical Features
- shortness of breath, crackles at lung bases, and CXR abnormal

Treatment (LMNOP)
- Lasix
- Morphine (decreases symptoms of dyspnea, venodilator, and afterload reduction)
- Nitrates (venodilator)
- Oxygen + non-invasive ventilation
- Position (sit patient up)
RESPIRATORY FAILURE

Clinical Features
- dyspnea, cyanosis, and evidence of obstructive lung disease
- earliest manifestations – tachypnea and hypoxemia (RR >25, pO₂ <60)
- pulmonary edema, and unexplained decrease in SaO₂

Treatment
- ABCs, O₂, ± positive pressure ventilation, and intubation
- bronchodilators, and diuretics to treat CHF
- adequate blood pressure to maintain pulmonary perfusion
- if these measures fail to keep PaO₂ >60, consider ARDS (see Respiratory, R26)

Cardiac Complications
- abnormal ECGs common in post-operative period (compare to pre-operative ECG)
- common arrhythmias: supraventricular tachycardia, atrial fibrillation (secondary to fluid overload, PE, and MI)

MYOCARDIAL INFARCTION
- see Cardiology and Cardiac Surgery, C39
- surgery increases risk of MI
- incidence
  - 0.5% in previously asymptomatic men >50 yr old
  - 40-fold increase in men >50 yr old with previous MI

Risk Factors
- pre-operative HTN, CHF
- previous MI (highest risk ≤6 mo, but risk never returns to baseline)
- increased age
- intra-operative hypotension
- operations >3 h
- angina

Clinical Features
- majority of cases on day of operation or POD #3-4 (shifting of third space fluid back into intravascular compartment)
- often silent without chest pain, may only present with new-onset CHF (dyspnea), arrhythmias, and hypotension

Intra-Abdominal Abscess

Definition
- collection of pus walled-off from rest of peritoneal cavity by inflammatory adhesions and viscera

Etiology
- usually polymicrobial: Gram-negative bacteria, and anaerobes
  - consider Gram-positives if coexisting cellulitis

Risk Factors
- emergency surgery, and contaminated OR
- GI surgery with anastomotic leak
- poor healing risk factors (DM, poor nutrition, etc.)
- may occur POD #3 after laparotomy when third space fluid re-distribution occurs

Clinical Features
- persistent spiking fever, dull pain, and weight loss
- mass difficult to palpate
- peritoneal signs if abscess perforation and secondary peritonitis
- leukocytosis or leukopenia (immunocompromised, and elderly)
- co-existing effusion (pleural effusion with subphrenic abscess)
- common sites: pelvis, Morrison’s pouch (space between kidney and liver), subphrenic, paracolic gutters, lesser sac, peri-appendiceal, post-surgical anastomosis, diverticular, and psoas

Investigations
- CBC, blood cultures x2
- CT ± IV and water-soluble contrast
- DRE (pelvic abscess)

Treatment
- drain placement by interventional radiology (preferred), laparoscopy, and open drainage
- subsequent antibiotic coverage; ceftriaxone + metronidazole or piperacillin-tazobactam (Pip-Tazo)
**Paralytic Ileus**
- see *Bowel Obstruction*, GS26

**Delirium**
- see *Psychiatry, PS22* and *Neurology, N20*

---

**Thoracic Surgery**

**Hiatus Hernia**

---

**SLIDING HIATUS HERNIA (TYPE I)**
- herniation of both the stomach and the gastroesophageal (GE) junction into thorax
- 90% of esophageal hernias

**Risk Factors**
- age
- increased intra-abdominal pressure (e.g. obesity, pregnancy, coughing, and heavy lifting)
- smoking

**Clinical Features**
- majority are asymptomatic
- hernias frequently associated with GERD due to decreased competence of LES

**Complications**
- most common symptom is GERD
- other complications are rare and are related to reflux
- esophagitis (dysphagia, and heartburn)
- consequences of esophagitis (peptic stricture, Barrett’s esophagus, and esophageal carcinoma)
- extra-esophageal complications (aspiration pneumonitis/pneumonia, bronchospasm, cough, and laryngitis)

**Investigations**
- barium swallow, endoscopy (esophago-gastroscopy), or esophageal manometry (technique for measuring LES pressure)
- 24 h esophageal pH monitoring to quantify reflux
- endoscopy with biopsy to document type and extent of tissue damage and rule out esophagitis, Barrett’s esophagus, and cancer

**Treatment**
- lifestyle modification
  - stop smoking, weight loss, elevate head of bed, no meals <3 h prior to sleeping, smaller and more frequent meals, avoid alcohol, coffee, mint, and fat
• medical
  • antacid, H2-antagonist, PPI, prokinetic agent
• surgical (<15%)
  • consider if: volume regurgitation, patient unwilling or unable to stay on PPI indefinitely, suboptimal medical therapy, complications of GERD such as pharyngitis, esophageal stricture, recurrent nocturnal aspiration, Barrett’s esophagus, patient preference
• hiatus hernia repair and fundoplication
  • anti-reflux procedure (usually laparoscopic)
  • fundus of stomach is wrapped around the lower esophagus and sutured in place
    • 360 degree wrap: Nissen Fundoplication, 270 degree wrap: Toupet, 180 degree wrap: Dor
  • complications: dysphagia, gas bloat, diarrhea, recurrence
  • dysphagia and gas bloat may be less with partial fundoplications (Toupet/Dor)
  • 90% success rate for alleviating GERD

PARAESOPHAGEAL HIATUS HERNIA (TYPE II)
• see Figure 6
• herniation of all or part of the stomach through the esophageal hiatus into the thorax with an undisplaced GE junction
• least common esophageal hernia (<10%)

Clinical Features
• usually asymptomatic due to normal GE junction
• pressure sensation in lower chest, dysphagia

Complications
• hemorrhage, incarceration, strangulation (gastric volvulus), obstruction, gastric stasis ulcer (Cameron’s lesion – causes Fe-deficiency anemia)

MIXED HIATUS HERNIA (TYPE III)
• see Figure 6
• second most common type of hernia – combination of types I and II
• includes giant hernias or intrathoracic stomach
• rare incidence of gastric volvulus (Borschadt’s Triad: chest pain, retching, inability to pass NG tube)
• majority present with long-standing Fe-deficiency anemia of unknown etiology
• symptoms commonly include reflux or heartburn
• most common symptoms: abnormal postprandial fullness after normal-sized meal, chest pain or retrosternal discomfort (gastric angina), and bloating
• can present with gastric outlet obstruction or gastric necrosis secondary to strangulation in the setting of gastric volvulus

Treatment
• surgery to address symptoms or treat/prevent complications
• reduce hernia and excise hernia sac, repair defect at hiatus, and anti-reflux procedure (e.g. Nissen fundoplication)
• may consider suturing stomach to anterior abdominal wall (gastropexy)
• in very elderly patients at high surgical risk consider PEG (percutaneous endoscopic gastrostomy) to anchor the stomach in the abdomen

TYPE IV HERNIA
• herniation of stomach and other abdominal organs into thorax: colon, spleen, and small bowel
• Fe-deficiency anemia is common

Esophageal Perforation

Etiology
• iatrogenic (most common)
  • endoscopic, dilatation, biopsy, intubation, operative, and NGT placement (rare)
• barogenic
  • trauma
  • repeated, forceful vomiting (Boerhaave’s syndrome)
  • other: convulsions, defecation, or labour (rare)
• ingestion injury
  • foreign body or corrosive substance
  • carcinoma

Clinical Features
• neck or chest pain
• fever, tachycardia, hypotension, dyspnea, and respiratory compromise
• subcutaneous emphysema, pneumothorax, pleural effusion, and hematemesis

Investigations
• CXR: pneumothorax, pneumomediastinum, pleural effusion, subdiaphragmatic air, and widened mediastinum
PET scan more sensitive than CT in detecting metastatic disease
full metastatic workup (CXR, bone scan, CT head, CT chest/abdomen/pelvis, and LFTs, etc.)
bronchoscopy ± thoracoscopy
mortality 10-50% dependent on timing of diagnosis
if early stage (non-transmural and without evidence of nodal disease)
barium swallow: shows narrowing – suggestive but not diagnostic
endoscopic biopsy and assess resectability
both SCC and adenocarcinoma use TNM staging system but have separate stage groupings according to histology
endoscopic U/S (EUS)
visualize local disease
regional nodal involvement (number of nodes may be more important than location)
bronchoscopy ± thoracoscopy
rule out airway invasion in tumours of the upper and mid esophagus
full metastatic workup (CXR, bone scan, CT head, CT chest/abdomen/pelvis, and LFTs, etc.)
PET scan more sensitive than CT in detecting metastatic disease
if early stage (non-transmural and without evidence of nodal disease)
endoscopic mucosal resection can be considered for early mucosal cancer or high grade dysplasia
esophagectomy (transthoracic or trans-hiatal approach) and lymphadenectomy
anastomosis in chest or neck
stomach most often used for reconstruction; may also use colon
adjuvant chemotherapy ± radiation usually recommended for post-operative node-positive disease

Esophageal Carcinoma

Epidemiology
M:F = 3:1
onset 50-60 yr of age
upper (20-33%), middle (33%), and lower (33-50%)
main types
most common worldwide: SCC in upper 2/3 of esophagus
most common in Western countries: adenocarcinoma in distal 1/3 of esophagus

Risk Factors
SCC
underlying esophageal disease such as strictures, diverticula, and achalasia
smoking, alcohol, and hot liquids
more common in black and Asian populations
adenocarcinoma
Barrett’s esophagus (most important), smoking, obesity (increased reflux), and GERD
more common in Caucasian populations

Clinical Features
progressive dysphagia (mechanical): first solids then liquids
odynophagia then constant pain
constitutional symptoms
regurgitation and aspiration (aspiration pneumonia)
hematemesis and anemia
direct, hematogenous, or lymphatic spread
trachea (coughing), recurrent laryngeal nerves (hoarseness, vocal paralysis), aortic, liver, lung, bone, celiac, and mediastinal nodes

Investigations and Staging
barium swallow: shows narrowing – suggestive but not diagnostic
endoscopic biopsy and assess resectability
both SCC and adenocarcinoma use TNM staging system but have separate stage groupings according to histology
endoscopic U/S (EUS)
visualize local disease
regional nodal involvement (number of nodes may be more important than location)
bronchoscopy ± thoracoscopy
rule out airway invasion in tumours of the upper and mid esophagus
full metastatic workup (CXR, bone scan, CT head, CT chest/abdomen/pelvis, and LFTs, etc.)
PET scan more sensitive than CT in detecting metastatic disease

Treatment
supportive if rupture is contained (see sidebar for Cameron’s criteria)
surgical
<24 h from perforation
primary closure of a healthy esophagus with buttressed intercostal muscle flap or resection of diseased esophagus
>24 h from perforation or non-viable wound edges
diversion and exclusion followed by delayed reconstruction (i.e. esophagostomy proximally, close esophagus distally, and gastrostomy/jejunostomy for decompression/feeding)

Complications
sepsis, abscess, fistula, empyema, mediastinitis, and death
post-operative esophageal leak
mortality 10-50% dependent on timing of diagnosis

E. Thoracoabdominal thoracotomy
D. Lateral thoracotomy
C. Anterolateral thoracotomy
B. Transverse thoracotomy (clam shell)
A. Median sternotomy

Perioperative Chemoradiotherapy vs. Primary Surgery for Resectable Adenocarcinoma of the Stomach, Gastroesophageal Junction, and Lower Esophagus

Study: Review of RCTs to examine the effect of perioperative chemotherapy for gastroesophageal adenocarcinoma on survival and other clinically relevant outcomes.
Results/Conclusions: 14 RCTs, 2422 participants.
1) Perioperative chemotherapy was associated with a significantly longer overall survival (HR 0.81, 95% CI 0.73 to 0.90, a relative survival increase of 19% and an absolute increase of 9%).
2) Tumours of the GE junction showed a more pronounced response to perioperative chemotherapy compared to other sites.
3) Combined chemoradiotherapy was more effective for tumours of the esophagus and GE junction compared to chemotherapy alone.
4) Perioperative chemotherapy was more effective in younger patients and was associated with longer disease-free survival, higher rates of R0 resection, and a more favourable tumour stage upon resection.
5) Resection with negative margins is a strong predictor of survival.
• if locally advanced (locally invasive disease or nodal disease on CT or EUS)
  • multimodal therapy
    • concurrent external beam radiation and chemotherapy (cisplatin and 5-FU)
    • possibility of curative esophagectomy after chemoradiation if disease responds well
  • if unable to tolerate multimodal therapy or if highly advanced disease, consider palliative resection, brachytherapy, or endoscopic dilatation/stenting/laser ablation for palliation
• if present with distant metastatic disease
  • treat with systemic therapy and treat symptoms (esophageal stent)

Prognosis
• TNM status - usually poor because presentation is usually at advanced stage

OTHER DISORDERS
• esophageal motor disorders (see Gastroenterology, G8)
• esophageal varices (see Gastroenterology, G29)
• Mallory-Weiss tear (see Gastroenterology, G29)

Thymoma

Epidemiology
• rare neoplasms in thymus including both thymoma and thymic carcinoma
• patients between 40 and 60 yr
• M = F

Risk Factors
• no known risk factors, strong association with myasthenia gravis and other paraneoplastic syndromes

Clinical Feature
• frequently asymptomatic: incidental finding on imaging
• symptoms related to tumour size and location or myasthenia gravis: chest pain, SOB, cough, and phrenic nerve palsy
• ddx includes intrathoracic goitre, lymphoma, and other anterior mediastinal tumours (see Respirology, R22)

Investigations
• CT chest (and/or MRI)
• Germ cell tumour markers (β-hCG, alpha fetoprotein), thyroid function, and PFTs

Treatment
• for patients with resectable disease
  • surgical resection of thymus via median sternotomy or VATS depending on the size
  • post-operative radiation based on Masaoka staging
  • Masaoka I: completely encapsulated; II: invasion beyond capsule; III: into another organ; IVa pleural/pericardial mets, IVb hematogeneous/lymphatic mets
  • radiation considered for stage II/III disease
• for non-surgical patients
  • multimodal therapy including neoadjuvant or palliative chemotherapy and post-operative chemoradiotherapy if de-bulking procedure feasible

Prognosis
• depends upon stage of disease and resectability
• generally slow growing tumours and have good prognosis, however thymic carcinomas more aggressive and have poorer prognosis

Pleura, Lung, and Mediastinum

• see Respirology, R22

Complicated Effusion

• persistent bacteria in the pleural space but fluid is non-purulent
• neutrophils, pleural fluid acidosis (pH <7.00), and high LDH
• often no bacteria grown since rapidly cleared from pleural space
• fibrin layer leading to loculation of pleural fluid
• treatment: antibiotics depending on Gram stain and chest tube drainage

Empyema

Definition
• pus in pleural space or an effusion with organisms seen on a Gram stain or culture (e.g. pleural fluid is grossly purulent)
• positive culture is not required for diagnosis
Etiology
- contiguous spread from lung infection (most commonly anaerobes) or infection through chest wall (e.g., trauma, surgery)

Signs and Symptoms
- fever, pleuritic chest pain

Investigations
- CT chest
- thoracentesis
  - PMNs (lymphocytes in TB) ± visible organisms on Gram stain

Treatment
- antibiotic therapy for at least 4-6 wk (rarely effective alone)
- complete pleural drainage with chest tube
- if loculated, more difficult to drain – may require surgical drainage with video-assisted thorascopic surgery (VATS), or removal of fibrin coating (surgical or tPA/DNAse) to allow lung re-expansion (decoration)

Pneumothorax

Definition
- presence of air in the pleural space

Pathophysiology
- entry of air into pleural space raises intrapleural pressure causing partial lung deflation

Etiology
- traumatic: penetrating or non-penetrating chest injuries
- iatrogenic: central venous catheter, thoracentesis, mechanical ventilation with barotrauma
- spontaneous: no history of trauma
  - primary (no underlying lung disease)
    - spontaneous rupture of apical subpleural bleb (packets of air) of lung into pleural space
    - smoker, male, family history, Marfan’s syndrome
  - secondary (underlying lung disease)
    - rupture of subpleural bleb which migrates along bronchioalveolar sheath to the mediastinum then to the intrapleural space
    - necrosis of lung tissue adjacent to pleural surface
    - pneumonia, abscess, PCP, lung CA, COPD, CF, TB, LAM, Pulmonary Langerhans cell histiocytosis (PLCH)

Signs and Symptoms
- can be asymptomatic
- acute-onset pleuritic chest pain, dyspnea
- tachypnea, tachycardia
- tracheal deviation (contralateral deviation in tension pneumothorax)
- ipsilateral diminished chest expansion
- decreased tactile/vocal fremitus
- hyperresonance
- ipsilateral diminished breath sounds

Investigations
- CXR
  - small: separation of visceral and parietal pleura seen as fine crescentic line parallel to chest wall at apex
  - large: decreased density and decreased volume of lung on side of pneumothorax
  - see Medical Imaging, MI9

Treatment
- primary spontaneous pneumothorax
  - stable, small (<3 cm), minimal symptoms: observation + O2
  - symptomatic or large (>3 cm): aspiration
- unstable/tension pneumothorax: needle decompression then chest tube, and VATS if unsuccessful (25-50%)
- secondary spontaneous pneumothorax
  - stable, small (<3 cm), minimal symptoms: observation + O2
  - symptomatic, large, or unstable: chest tube, and VATS if unsuccessful
Tube Thoracostomy

Indications
- to drain abnormal large-volume air or fluid collections in the pleural space
  - hemothorax, pleural effusion, chylothorax, and empyema
  - pneumothorax, if:
    - large or progressive
    - patient is on mechanical ventilation
    - bronchopleural fistula
    - tension pneumothorax
- to treat symptomatic and/or recurrent pleural effusion
  - see Respirology, R23
  - for long-term drainage of malignant effusions use: 1. Tunneled pleural catheter; 2. Pleural drainage and chemical pleurodesis
- via facilitation of pleurodesis (obliteration of the pleural space by instilling talc or betadine to cause fibrosis and adherence of parietal and visceral pleura)

Complications
- overall complications are rare (1-3%)  
- malposition (most common complication), especially by inexperienced operators
  - tubes may dissect along the external chest wall, or may be placed below the diaphragm
- bleeding (anticoagulation is a relative contraindication)
- local infection, empyema
- perforation of lung parenchyma or vasculature
- risk of re-expansion pulmonary edema when large volumes of air or fluid are drawn off quickly (>1.0-1.5 L)

Lung Cancer

Classification
- lung tumours can be classified as primary or secondary, benign or malignant, endobronchial or parenchymal
- bronchogenic carcinoma (epithelial lung tumours) are the most common type of primary lung tumour (other types make up less than 1%)
  - small cell lung cancer (SCLC): 10-15%
  - non-small-cell lung cancer (NSCLC): 85-90%
    - squamous cell carcinoma: arise from the proximal respiratory epithelium
    - adenocarcinoma: incidence is increasing; most common subtype in nonsmokers
      - mucinous adenocarcinoma: grows along the alveolar wall in the periphery; may arise at sites of previous lung scarring
      - large cell undifferentiated cancer: diagnosis of exclusion
  - benign epithelial lung tumours can be classified as papillomas or adenomas

</table>

Risk Factors
- cigarette smoking: the relative risk of developing lung cancer is 10-30 times higher for smokers than for nonsmokers
- risk of lung cancer increases with number of cigarettes smoked per day (linear) and duration of smoking (exponential)
- other risk factors include cigar smoking, pipe smoking, second-hand smoke, asbestos without smoking (relative risk is 5), asbestos with smoking (relative risk is 92), metals (e.g. chromium, arsenic, nickel), radon gas, ionizing radiation, and genetics
Signs and Symptoms

- may be due to primary lesion, metastasis, or paraneoplastic syndrome

- primary lesion
  - cough (75%): beware of chronic cough that changes in character
  - dyspnea (60%)
  - chest pain (45%)
  - hemoptysis (35%)
  - other pain (25%)
  - clubbing (21%)
- constitutional symptoms: anorexia, weight loss, fever, and fatigue

- metastasis
  - lung, hilum, mediastinum, pleura: pleural effusion, atelectasis, wheezing, postobstructive pneumonia
  - pericardium: pericardial effusion, pericardial tamponade
  - esophageal compression: dysphagia
  - phrenic nerve: paralyzed diaphragm
  - recurrent laryngeal nerve: hoarseness
  - superior vena cava syndrome
    - obstruction of SVC causing neck and facial swelling, as well as dyspnea and cough
    - other symptoms: hoarseness, tongue swelling, epistaxis, and hemoptysis
    - physical findings: dilated neck veins, increased number of collateral veins covering the anterior chest wall, cyanosis, edema of the face, arms, and chest, Pemberton’s sign (facial flushing, cyanosis, and distension of neck veins upon raising both arms above head)
    - milder symptoms if obstruction is above the azygos vein
  - lung apex (Pancoast tumour): Horner’s syndrome, brachial plexus palsy (most commonly C8 and T1 nerve roots)
  - rib and vertebrae: erosion
  - distant metastasis to brain, bone, liver, and adrenals

- paraneoplastic syndromes
  - a group of disorders associated with malignant disease, not related to the physical effects of the tumour itself
  - most often associated with SCLC

Table 6. Paraneoplastic Syndromes

Investigations

- initial diagnosis
  - imaging: CXR, CT chest + upper abdomen, PET scan
  - cytology: sputum
  - biopsy: bronchoscopy, EBUS, CT-guided percutaneous needle biopsy, mediastinoscopy

- staging workup
  - TNM staging system: T – primary tumour (size); N – regional lymph nodes; M – distant metastasis
  - blood work: electrolytes, LFTs, calcium, ALP
  - imaging: CXR, CT thorax and upper abdomen, bone scan, neuroimaging, PET scan
  - invasive: bronchoscopy (EBUS), mediastinoscopy, mediastinotomy, thoracotomy
  - screen adenocarcinoma for EGFR and ALK mutations

Postoperative Radiotherapy for NSCLC

Cochrane DB Syst Rev 2016;10:CD002142

Objective: Evaluate effects of postoperative radiotherapy on survival and recurrence in patients with completely resected NSCLC.

Methods: MEDLINE and CANCERLIT searches and trial registers for trials of surgery vs. surgery plus radiotherapy in patients with NSCLC.

Results: 14 trials, 2343 participants. Postoperative radiotherapy had a significant adverse effect on survival (HR 1.18, 95% CI 1.07-1.31). This was equivalent to an absolute detriment of 5% at two years, reducing survival from 58 to 55%. Postoperative radiotherapy increased risk of recurrence (HR 1.10, 95% CI 0.99-1.21).

Conclusions: Postoperative radiotherapy is detrimental to those with completely resected NSCLC and should not be used in the routine treatment.

|         | IA    | T1a-1bN0M0 |                                                                                                           | 43-58            |
|         | IB    | T2aN0M0 |                                                                                                           | 36-46            |
|         | IIA   | T1a-T2a,N1M0 or T2bN0M0 |                                                                                                           |                  |
|         | IIB   | T2bN1M0 or T3N0M0 |                                                                                                           | 25-36            |
|         | IIIA  | T1a-T2bN2M0 or T3N1-2M0 or T4N0-1M0 | Combined modality approach (chemotherapy, radiation therapy and sometimes surgical resection) | 19-24            |
|         | IIIB  | T4N2M0 or T1-4N2M0 |                                                                                                           | 7-9              |
|         | IV    | T1-4N0-3M1a-1b | Systemic therapy or molecularly targeted therapy or symptom-based palliative management (radiation); isolated metastasis may be resected | 2-13             |

* Depends on clinical vs. pathologic stage

Refer to AJCC Cancer Staging Manual, 7th ed. 2010 for complete TNM classification

Treatment

- options include surgery, radiotherapy, chemotherapy, and palliative care for end-stage disease
- surgery not usually performed for SCLC since it is generally non-curable
- contraindications for surgery
  - spread to contralateral lymph nodes or distant sites
  - patients with potentially resectable disease must undergo mediastinal node sampling since CT thorax is not accurate in 20-40% of cases
  - poor pulmonary status (e.g. unable to tolerate resection of lung)
  - post-op estimated FEV1 and DLCO must be at least 40% of predicted to tolerate surgery
  - chemotherapy (used in combination with other treatments)
  - common agents: etoposide, platinum agents (e.g. cisplatinam), ifosfamide, vincristine, anthracyclines, phtalaxel, irinotecan, gefitinib (an endothelial growth factor receptor inhibitor)
- complications
  - acute: tumour lysis syndrome, infection, bleeding, myelosuppression, hemorrhagic cystitis (cyclophosphamide), cardiotoxicity (doxorubicin), renal toxicity (cisplatin), peripheral neuropathy (vincristine)
  - chronic: neurologic damage, leukemia, additional primary neoplasms

Approach to the Solitary Pulmonary Nodule

- see Medical Imaging, MI7

Definition

- a round or oval, sharply circumscribed radiographic lesion up to 3 cm, which may or may not be calcified, and is surrounded by normal lung
- can be benign or malignant

Table 8. Differential Diagnosis for Benign vs. Malignant Solitary Nodule

</tbody>
</table>

Prevention

- Smoking cessation
- Avoidance of exposures
- Early detection

Terminology

- "nodule": <3 cm
- "mass": >3 cm

Hamartomas

- 10% of benign lung lesions
- Composed of tissues normally present in lung (fat, epithelium, fibrous tissue, and cartilage), but they exhibit disorganized growth
- Peak incidence is age 60, more common in men
- Usually peripheral and clinically silent
- CXR shows clustered “popcorn” pattern of calcification (pathognomonic for hamartoma)

Adenocarcinoma present in a non-smoker may be due to endothelial growth factor receptor mutation

Corona Radiata Sign on Chest CT

- Fine striations that extend linearly from a nodule in a spiculated fashion
- Highly associated with malignancy

Carcinoids

- Early onset (40-60 yr)
- Most are central and can produce symptoms and signs of bronchial obstruction
- Hemoptysis is present in ~50% of cases

Pulmonary neoplasms may present as a solitary pulmonary nodule identified incidentally on a radiographic study (~10% of cases) or as symptomatic disease (most cases)
Investigations
- CXR: always compare with previous CXR
- CT densitometry and contrast enhanced CT of thorax
- sputum cytology: usually poor yield
- biopsy (bronchoscopic or percutaneous) or excision (thoracoscopy or thoracotomy): if clinical and radiographic features do not help distinguish between benign or malignant lesion
  - if at risk for lung cancer, biopsy may be performed regardless of radiographic features
  - if a biopsy is non-diagnostic, whether to observe, re-biopsy, or resect will depend on the level of suspicion
- watchful waiting: repeat CXR and/or CT scan at 3, 6, 12 mo
- PET scan can help distinguish benign from malignant nodules

Lung Transplantation

Conditions Leading to Transplantation
- chronic acquired lung disease: COPD
- genetic: CF, and emphysema due to α-1 antitrypsin deficiency
- idiopathic interstitial pneumonias: IPF, and nonspecific interstitial pneumonitis
- HTN-related: idiopathic pulmonary arterial HTN (IPAH), secondary pulmonary HTN, and Eisenmenger's syndrome
- other: sarcoidosis, lymphangioleiomyomatosis, and pulmonary Langerhans cell histiocytosis

Clinical Indications
- transplantation should be considered for patients with advanced lung disease refractory to maximal medical or surgical therapy
- patients who are symptomatic during activities of daily living and have risk of death >50% over the next 2 yr
Criteria for Transplantation
- Lung allocation score based on: 1) post-transplant survival measure, and 2) waiting list urgency measure
- Transplant benefit = post-transplant survival (days) – waitlist survival (days)

Contraindications
- Unstable medical condition such as acute sepsis or poorly controlled dysfunction of another organ system (e.g. heart, liver, kidney or brain)
- Malignancy in the last 2 yr
- Uncorrected CAD with end organ ischemia or CAD not amenable to revascularization
- Significant chest wall/spinal deformity
- Active cigarette smoking, and BMI ≥35
- HIV infection, ongoing HBV, HCV, or TB infections
- Inadequate social supports, functional limitation to participate in rehab, psychological issues reducing compliance with medical regimen

Post-Operative Complications
- Primary graft dysfunction (main cause is ischemia-reperfusion injury)
- Airway anastomotic complications (focal infection, bronchial necrosis and dehiscence, excess granulation tissue, tracheobronchomalacia, stenosis, and fistula)
- Chronic graft dysfunction (bronchiolitis obliterans syndrome, and restrictive allograft syndrome)
- Infectious complications (bacterial, fungal, CMV, community-acquired respiratory viruses, and mycobacteria)
- Malignancy (non-melanoma skin cancer, post-transplant lymphoproliferative disease, colon, breast, Kaposi's sarcoma, and bladder)

Prognosis
- Median survival for all adult recipients: 5.7 yr
- 1 yr survival: COPD > IPF > IPAH
- 10 yr survival: CF, α-1 antitrypsin deficiency > IPAH > COPD, IPF

Chronic Obstructive Pulmonary Disease
- See Respirology, R9

Treatment
- Indications for surgical management
  - Dyspnea despite maximal medical therapy and pulmonary rehabilitation
  - CT showing hyperinflation and heterogeneous distribution of emphysema predominant in the upper lung zone
  - May be used as a bridging procedure to lung transplantation
- Contraindications
  - Age > 75, cigarette smoking within the prior 6 mo, higher risk of surgical mortality
  - Homogeneously distributed emphysematous changes without areas of preserved lung tissue
  - Diffusing capacity of lung for carbon monoxide < 20% of predicted, PaCO₂ > 60 mmHg, PaO₂ < 45 mmHg
- Surgical procedures
  - Lung volume reduction surgery: wedge excision of emphysematous tissue
  - Bilateral or unilateral, thoracotomy or VATS

Complications of Treatment
- Air leak: may require reintubation and mechanical ventilation
- Arrhythmias, pneumonia

Prognosis
- Worse early mortality but better exercise capacity and quality of life with LVRS
Peptic Ulcer Disease

GASTRIC ULCERS
- see Gastroenterology, G11

Indications for Surgery
- refractory to medical management
- suspicion of malignancy (even if biopsy benign)
- complications of PUD: obstruction, perforation, and bleeding (3x greater risk compared to duodenal ulcers)
- surgery increasingly rare due to H. pylori eradication, medical treatment and endoscopic treatments (injection therapy with adrenaline, polidocanol or fibrin glue) or coagulation therapy (heater probe or argon plasma)

Procedures
- ligation of bleeding vessels
- distal gastrectomy with ulcer excision: Billroth II, Roux-en-Y gastrojejunostomy or Billroth I (rarely) reconstruction
- vagotomy and pyloroplasty only if acid hypersecretion (very rare)
- wedge resection if possible
- biopsy for suspicion of malignancy, followed by gastroscopy to minimize further bleeding and aid with healing

DUDENAL ULCERS
- see Gastroenterology, Bleeding Peptic Ulcer, G12, and Peptic Ulcer Disease, G11
- most within 2 cm of pylorus (duodenal bulb)

Indications for Surgery
- hemorrhage, rebleed in hospital, perforation, gastric outlet obstruction
- refractory to medical and endoscopic management

Procedures
- omental (Graham) patch: plication of ulcer supported by overlying omental patch
- oversewing of bleeding ulcer ± pyloroplasty
- treat with H.pylori eradication protocol post operatively

Complications of Gastric Surgery
- retained antrum
- fistula (gastrocolic/gastrojejunal)
- dumping syndrome, postvagotomy diarrhea, afferent loop syndrome

</tbody>
</table>
Gastric Carcinoma

Epidemiology
- 5th most common cancer in the world
- M:F = 3:2
- most common age group = 50-59 yr
- incidence has decreased by 2/3 in past 50 yr
- incidence of adenocarcinoma <10 (US) vs. 40 (Japan, Korea) per 100,000 (incidence highest in Asia, Latin America, and Caribbean)

Risk Factors
- compensatory epithelial cell proliferation via gastric atrophy from:
  - H. pylori, causing chronic atrophic gastritis
  - pernicious anemia associated with achlorhydria and chronic atrophic gastritis
  - previous partial gastrectomy (>10 yr post-gastrectomy)
- host-related factors
  - blood type A
  - hereditary nonpolyposis colorectal cancer (HNPCC), hereditary diffuse gastric carcinoma (HDGC)
  - gastric adenomatous polyps
  - hypertrophic gastropathy
  - genetic syndromes: hereditary diffuse gastric cancer E-cahedrin (CDH-1) gene
- patient and lifestyle factors: high BMI, smoking, alcohol, smoked food, and nitrosamines

Clinical Features
- clinical suspicion
  - ulcer fails to heal
  - lesion on greater curvature of stomach or cardia
- asymptomatic, insidious, or late onset of symptoms
  - postprandial abdominal fullness, pseudoachalasia (in older patients), vague epigastric pain
  - anorexia or weight loss
  - burping, N/V, dyspepsia, and dysphagia
  - hepatomegaly, epigastric mass (25%) hematemesis, fecal occult blood, melena, and iron-deficiency anemia
- metastasis
  - peritoneum, ovarian, liver, lung, and brain

Investigations
- OGD and biopsy; consider EUS to assess pre-operative T-stage and N-stage
- CT chest/abdomen/pelvis (for Metastatic Workup see Table 14)

Table 12. TNM Classification System for Staging of Gastric Carcinoma (AJCC/UICC 2017, 8th edition)

</tbody>
</table>

Treatment
- adenocarcinoma
  - proximal lesions
    - total gastrectomy and Roux-en-Y esophagojejunostomy
  - distal lesions
    - subtotal gastrectomy: wide margins, en bloc removal of omentum and lymph nodes with Roux-en-Y or Billroth II reconstruction
  - adjuvant therapies
    - perioperative chemotherapy or post-operative chemoradiotherapy in addition to surgery is standard of care in curative intent strategy
- palliation
  - limited gastric resection or endoscopic stenting to decrease bleeding and relieve obstruction, enables the patient to eat
  - radiation therapy
  - studies are showing larger role for adjuvant/neoadjuvant and palliative chemotherapy
- lymphoma
  - H. pylori eradication, chemotherapy ± radiation, and surgery in limited cases (perforation, bleeding, and obstruction)
Gastrointestinal Stromal Tumour

Epidemiology
- most common mesenchymal neoplasm of GI tract
- derived from interstitial cells of Cajal (cells associated with Auerbach’s plexus that have autonomous pacemaker function which coordinate peristalsis throughout the GI tract)
- 75-80% associated with tyrosine kinase (c-KIT) mutations
- most common in stomach (50%) and proximal small intestine (25%), but can occur anywhere along GI tract
- typically present with vague abdominal mass, feeling of abdominal fullness, or with secondary symptoms of bleeding and anemia
- often discovered incidentally on CT, laparotomy, or endoscopy

Risk Factors
- Carney’s triad: GISTs, paraganglioma, and pulmonary chondroma
- Type I neurofibromatosis

Investigations
- pre-operative biopsy (endoscopic ultrasound): useful for indeterminate lesions (not recommended if high index of suspicion for GIST)
- contrast-enhanced CT is preferred Imaging for screening and staging; MRI if IV contrast not feasible

Treatment
- surgical resection if >2 cm; follow with serial endoscopy if <2 cm and resect if growing or symptomatic
- localized GIST
  - surgical resection with preservation of intact pseudocapsule
  - lymphadenectomy NOT required, as GISTs rarely metastasize to lymph nodes
  - consider adjuvant treatment with imatinib (Gleevec) if high risk of relapse (large, >4 cm with significant mitotic activity)
- advanced disease (i.e. metastasizes to liver and/or peritoneal cavity)
  - palliative intent chemotherapy with imatinib
  - metastectomy may be considered for liver limited disease

Prognosis
- risk of metastatic potential depends on
  - tumour size (worse if >10 cm)
  - mitotic activity (worse if >5 mitotic figures or 50/hpf)
  - degree of nuclear pleomorphism
  - location: with identical sizes, extra-gastric location has a higher risk of progression than GISTs in the stomach
- metastases to liver, omentum, peritoneum; nodal metastases rare

Bariatric Surgery

- weight reduction surgery for morbid obesity
- indications: BMI ≥40 without illness or BMI ≥35 with 1+ serious comorbidity (e.g. DM, CAD, sleep apnea, GERD, or severe joint disease)

Surgical Options
- combination malabsorptive and restrictive
  - laparoscopic Roux-en-Y gastric bypass (most common, most effective; higher complication rates)
    - small gastric pouch (restrictive), from distal stomach, anastomosed with Roux limb of small bowel (malabsorptive); connect to bilipancreatic limb to maintain digestive enzymes and bile
    - restrictive laparoscopic sleeve gastrectomy (only consider for severe obesity)
    - creation of tubular stomach via removal of majority of greater curvature
    - laparoscopic adjustable gastric banding (modest expected weight loss, declining in popularity)
    - inflatable silicone band around fundus, adjustable via subcutaneous port
- malabsorptive
  - biliopancreatic diversion with duodenal switch
  - anastomosis of stomach to distal ileum, anastomosis of biliopancreatic limb to terminal ileum

Complications
- perioperative mortality ~1% (anastomotic leak with peritoneal signs, PE)
- obstruction at enterointeroanastomosis (see Complications of Gastric Surgery, GS18)
- staple line dehiscence
- dumping syndrome
- cholelithiasis due to rapid weight loss (20-30%)
- band abscess (if long-term)
Complications of Gastric Surgery

- most resolve within 1 yr

Alkaline Reflux Gastritis
- duodenal contents (bilious) reflux into stomach causing gastritis ± esophagitis
- treatment
  - medical: H2-blocker, metoclopramide, cholestyramine (bile acid sequestrant)
  - surgical: conversion of Billroth I or II to Roux-en-Y

Afferent Loop Syndrome
- accumulation of bile and pancreatic secretions causes intermittent mechanical obstruction and distention of afferent limb
- clinical features
  - early postprandial distention, RUQ pain, nausea, bilious vomiting, anemia
  - treatment: surgery (conversion to Roux-en-Y increases afferent loop drainage)

Dumping Syndrome
- early: 15-30 min post-prandial
  - etiology
    - rapid emptying of hyperosmotic chyme leads to jejunal distention, stimulating release of vasoactive hormones
  - clinical features
    - post-prandial epigastric cramping, bloating, emesis, nausea, and vasomotor symptoms (dizziness, palpitations, tachycardia, diaphoresis)
  - treatment
    - frequent small meals high in fibre and protein, low in carbohydrates; avoidance of liquids with meals
    - last resort is interposition of antiperistaltic jejunal loop between stomach and small bowel to delay gastric emptying
- late: 3 h post-prandial
  - etiology: hypoglycemia following postprandial insulin peak
  - treatment: small snack 2 h after meals

Blind-Loop Syndrome
- bacterial overgrowth of colonic Gram-negative bacteria in afferent limb
- clinical features
  - anemia/weakness, diarrhea, malnutrition, abdominal pain, and hypocalcemia
- treatment: broad-spectrum antibiotics, and surgery (conversion to Billroth I)

Postvagotomy Diarrhea
- up to 25%
- bile salts in colon inhibit water resorption
- treatment: medical (cholestyramine), and surgical (reversed interposition jejunal segment)

Small Intestine

Small Bowel Obstruction

Mechanical Small Bowel Obstruction

Pathophysiology
- obstruction → gas and fluid (swallowed or GI secretions) accumulate proximal to site of obstruction and distal decompression → intestinal activity increases to overcome obstruction → colicky pain and diarrhea (initially)
- bowel wall edema and disruption of normal bowel absorptive function can lead to increased intraluminal fluid, transudative fluid loss into peritoneal cavity, and electrolyte disturbances, which is worsened by vomiting
- increase intramural pressure can lead to impaired microvasculard perfusion leading to intestinal ischemia and necrosis (strangled bowel obstruction)

Etiology

Table 13. Common Causes of SBO

<table>
<thead>
<tr>
<th>Intraluminal</th>
<th>Intramural</th>
<th>Extramural</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intussuction</td>
<td>Crohn’s</td>
<td>Adhesions from previous surgeries (75% SBO)</td>
</tr>
<tr>
<td>Gallstones</td>
<td>Radiation stricture</td>
<td>Incarcerated hernia</td>
</tr>
<tr>
<td>Bezoars</td>
<td>Adenocarcinoma</td>
<td>Peritoneal carcinomatosis</td>
</tr>
</tbody>
</table>
• three types
  • partial SBO: only a portion of intestinal lumen is occluded, allows passage of some gas & fluid, low risk of strangulation
  • complete SBO: the lumen of the intestine is occluded, no passage of gas or stool, at higher risk of strangulation
  • closed-loop obstruction: segment of intestine is obstructed both proximally and distally (e.g. volvulus), leading to rapid rise in intraluminal pressure from gas and fluid that cannot escape, high risk of strangulation due to bowel wall ischemia

**Risk Factors**

• prior abdominal or pelvic surgery
• abdominal wall or groin hernia
• history of malignancy
• prior radiation

**Clinical Features**

• 1) distinguish mechanical obstruction from ileus; 2) determine likely and easily reversible etiology of obstruction; 3) differentiate complicated (e.g. strangulated) obstruction
• symptoms: colicky abdominal pain, nausea/vomiting, obstipation
  • more feculent vomitus suggests more established obstruction because of bacterial overgrowth
  • passage of gas and/or stool that continues 6-12 h after onset of symptoms suggests partial rather than complete obstruction
• signs: abdominal distention (most prominent if obstruction at distal ileum), hyperactive proceeding to minimal bowel sound
• strangulated obstruction: abdominal pain disproportionate to physical exam findings suggest intestinal ischemia
  • may have tachycardia, localized abdominal tenderness, fever, marked leukocytosis, and lactate acidosis

**Investigations**

• radiological
  • abdominal x-ray (3 views): triad of dilated small bowel (>3 cm in diameter), air-fluid levels on upright film, paucity of air in colon (high sensitivity, low specificity as ileus and LBO can present similarly)
  • CT: discrete transition zone/point with proximal bowel dilation, distal bowel decompression, and intraluminal contrast does not pass the transition zone
    • most importantly to rule out ischemic bowel/strangulation; pneumatosis intestinalis (free air in bowel wall) and thickened bowel wall, air in portal vein, free intraperitoneal fluids, and differential wall enhancements (poor uptake of IV contrast into the wall of the affected bowel)
  • other
    • less used: upper GI series/small bowel series (if no cause apparent, i.e. no hernias, and no previous surgeries) or serial CTs with oral contrast
    • may consider U/S or MRI in pregnant patients
• laboratory
  • may be normal early in disease course
  • creatinine, and hematocrit to assess degree of dehydration
  • fluid, and electrolyte abnormalities; metabolic alkalosis due to frequent emesis; amylase elevated
  • if strangulation: leukocytosis with left shift, elevated lactate (late signs)

**Treatment**

• IV isotonic fluid resuscitation and urine output monitoring with catheter
• SBO related vomiting and decrease PO intake leads to volume depletion
• NG tube in the stomach for gastric decompression; decrease nausea, distention, and risk of aspiration from vomiting
• NPO
• Partial SBO/Crohn's/Carcinomatosis: conservative management with fluid resuscitation and NG tube decompression
  • 48 h of watchful waiting; if no improvement or develops complications, surgery
  • For Crohn's patients, consider GI consult for steroid management
• if no clinical features of ischemia, short course of conservative management with fluid resuscitation and NG tube decompression with frequent re-examination by surgical team
  • duration of observation varies from hours to a few days
  • if SBO fails to resolve, or if symptoms of ischemia develop, then surgery
• high risk for ischemia based on clinical symptoms: urgent surgery to prevent irreversible ischemia
  • early post-operative SBO: if bowel function does not return within 3-5 d after surgery; usually partial, extended conservative therapy (2-3 wk) with bowel rest, fluids, and TPN is appropriate
• surgery if presence of ischemia or perforation demonstrated
Prognosis
- related to etiology; mortality: non-strangulating <1%, strangulating 8% (25% if >36 h), ischemic = up to 50%

Prevention
- open surgery has four-fold increase in risk of SBO in 5 yr compared to laparoscopic surgery

**Paralytic Ileus**

Pathogenesis
- temporary, reversible impairment of intestinal motility; mostly frequently caused by:
  - abdominal operations, infections and inflammation, medications (opiates, anesthetics, psychotropics), and electrolyte abnormalities
  - passing gas is the most useful indicator
- NOT the same as intestinal pseudo-obstruction
  - chronic pseudo-obstruction refers to specific disorders that affect the smooth muscle and myenteric plexus, leading to irreversible intestinal dysmotility

Clinical Features
- symptoms and signs of intestinal obstruction without mechanical obstruction
  - bowel sounds are diminished or absent (in contrast to initial hyperactive bowel sounds in SBO)
  - may have liquid stools as well

Investigations
- routine post-operative ileus: expected, no investigation needed
- if ileus persists or occurs without abdominal surgery
  - review patient medications (especially opiates)
  - measure serum electrolyte to monitor for electrolyte abnormalities (including extended electrolytes like Mg, Ca, PO4)
  - CT scan to rule out abscess or peritoneal sepsis, or to exclude mechanical obstruction

Treatment
- most important: NPO + fluid resuscitation
- NGT decompression, correct causative abnormalities (e.g. sepsis, medications, and electrolytes), consider TPN for prolonged ileus
- post-operative: gastric and small bowel motility returns by 24-48 h, colonic motility by 3-5 d
- current interest in novel therapies such as gum chewing and pharmacologic therapy (e.g. alvimopan, an opioid antagonists)

**Intestinal Ischemia**

Etiology
- acute
  - arterio-occlusive mesenteric ischemia (AOMI)
    - thrombotic, embolic, and extrinsic compression (e.g. strangulating hernia)
  - non-occlusive mesenteric ischemia (NOMI)
    - mesenteric vasoconstriction secondary to systemic hypoperfusion (preserves supply to vital organs)
  - mesenteric venous thrombosis (MVT)
    - consider hypercoagulable state (i.e. rule out malignancy), and DVT (prevents venous outflow)
- chronic: usually due to atherosclerotic disease – look for CVD risk factors
- can lead to occlusion in vessels that supplies the small intestine and the large intestine

Clinical Features
- acute: severe abdominal pain out of proportion to physical findings, vomiting, bloody diarrhea, bloating, minimal peritoneal signs early in course, hypotension, shock, and sepsis
- chronic: postprandial pain (from mesenteric angina), fear of eating, and weight loss
- common sites: SMA supplied territory, “watershed” areas of colon – splenic flexure, left colon, and sigmoid colon

Investigations
- laboratory: leukocytosis (non-specific), and lactic acidosis (late finding)
  - amylase, lactate, CK, and ALP can be used to observe progress
  - hypercoagulability workup if suspect venous thrombosis
  - AXR: portal venous gas, intestinal pneumatosis, and free air if perforation
  - contrast CT: thickened bowel wall, luminal dilatation, SMA or SMV thrombus, mesenteric/portal venous gas, and pneumatosis
- CT angiography is the gold standard for acute arterial ischemia
**Small Bowel Obstruction**

**Treatment**
- fluid resuscitation, correct metabolic acidosis, NPO, NGT decompression of stomach, and prophylactic broad-spectrum antibiotics; avoid vasoconstrictors and digitalis
- exploratory laparotomy/laparoscopy to assess extent of viability ± segmental resection of necrotic intestine
  - if extent of bowel viability is uncertain, a second-look laparotomy 12-24 h later is mandatory
- angiogram, embolectomy/thrombectomy, bypass/graft, mesenteric endarterectomy, anticoagulation therapy, and percutaneous transluminal angioplasty ± stent

**Tumours of Small Intestine**

**BENIGN TUMOURS**
- 10x more common than malignant
- usually asymptomatic until large
- most common sites: terminal ileum and proximal jejunum
- polyps
  - adenomas
  - hamartomas
  - FAP (see Familial Colon Cancer Syndromes, GS38)
- juvenile polyps
- other: leiomyomas, lipomas, and hemangiomas

<td>TNM</td>
</tr>
</tbody>
</table>

**Carcinoid Syndrome Symptoms**
- FDR
- flushing
- diarrhea
- right-sided heart failure
**Short Gut Syndrome**

**Definition**
- reduced surface area (length) of small bowel causing insufficient intestinal absorption leading to diarrhea, malnutrition, and dehydration

**Etiology**
- acute mesenteric ischemia: resection of large amount of bowel at once
- Crohn's disease: cumulative resections
- malignancies

**Prognostic Factors**
- residual small bowel length, residual colon length (reabsorption of water and electrolytes and some reabsorption of nutrients), condition of the remnant small bowel (healthier bowel facilitate better reabsorption), presence of ileocecal valve (delay transition into colon leading to more reabsorption)
- resection of ileum is less tolerated than resection of jejunum (ileum reabsorbs bile salt and vitamin B12)

**Therapy**
- medical
  - TPN: replenish lost fluid and electrolytes in diarrhea
  - HT2R antagonist or PPI to prevent gastric acid secretion
  - antimitoty agent to prolong transit time in the small intestine
  - consider octreotide to decrease GI secretion and cholestyramine for bile acid absorption
- surgical: non-transplant
  - to slow transit time: small bowel segmental reversal, intestinal valve construction, or electrical pacing of small bowel
  - to increase intestinal length:
    - LILT (longitudinal intestinal lengthening and tailoring) procedure
    - STEP (serial transverse enteroplasty procedure) in dilated small bowels
- surgical: transplant
  - indication: life-threatening complication from intestinal failure or long-term TPN, including liver failure, thrombosis of major central veins, recurrent catheter-related sepsis, and recurrent severe dehydration

**Abdominal Hernia**

- see **Hiatus Hernia, GS13**

**Definition**
- defect in abdominal wall causing abnormal protrusion of intra-abdominal contents

**Epidemiology**
- M:F = 9:1
- lifetime risk of developing a hernia: males 20-25%, females 2%
- frequency of occurrence: 50% indirect inguinal, 25% direct inguinal, 8-10% incisional (ventral), 5% femoral, and 3-8% umbilical
- most common surgical disease of males

**Risk Factors**
- activities which increase intra-abdominal pressure
  - obesity, chronic cough, asthma, COPD, pregnancy, constipation, bladder outlet obstruction, ascites, and heavy lifting
- congenital abnormality (e.g. patent processus vaginalis, and indirect inguinal hernia)
- previous hernia repair, especially if complicated by wound infection
- loss of tissue strength and elasticity (e.g. hiatus hernia, aging, and repetitive stress)

**Clinical Features**
- mass of variable size
- tenderness worse at end of day, relieved with supine position or with reduction
- abdominal fullness, vomiting, constipation
- transmits palpable impulse with coughing or straining

**Investigations**
- physical examination usually sufficient
- U/S ± CT (CT required for obturator hernias, internal abdominal hernias, and Spigelian and/or femoral hernias in obese patients)
Abdominal Hernia

**Classification**
- complete: hernia sac and contents protrude through defect
- incomplete: partial protrusion through the defect
- internal hernia: sac herniating into or involving intra-abdominal structure
- external hernia: sac protrudes completely through abdominal wall
- strangulated hernia: vascular supply of protruded viscus is compromised (ischemia)
  - requires emergency repair
- incarcerated hernia: irreducible hernia, not necessarily strangulated
- Richter's hernia: only part of bowel circumference (usually anti-mesenteric border) is incarcerated or strangulated so may not be obstructed
  - a strangulated Richter's hernia may self-reduce and thus be overlooked, leaving a gangrenous segment at risk of perforation in the absence of obstructive symptoms
- sliding hernia: part of wall of hernia sac formed by retroperitoneal structure (usually colon)

**Anatomical Types**
- groin
  - direct and indirect inguinal, femoral
- pantaloon: combined direct and indirect hernias, peritoneum draped over inferior epigastric vessels
- epigastric: defect in linea alba above umbilicus
- incisional: ventral hernia at site of wound closure, may be secondary to wound infection
- other: Littre's (involving Meckel's), Amyand's (containing appendix), lumbar, obturator, peristomal, umbilical, Spigelian (ventral hernia through linea semilunaris)

**Complications**
- incarceration
- strangulation
  - small, new hernias more likely to strangulate
  - femoral >> indirect inguinal > direct inguinal
- intense pain followed by tenderness
- intestinal obstruction, gangrenous bowel, sepsis
- surgical emergency
- DO NOT attempt to manually reduce hernia if septic or if contents of hernial sac gangrenous. This will result in reduction of gangrenous contents and subsequent need for laparotomy

**Treatment**
- surgical treatment (herniorrhaphy) is only to prevent strangulation and evisceration, for symptomatic relief, for cosmesis; if asymptomatic can delay surgery
- repair may be done open or laparoscopic and may use mesh for tension-free closure
  - avoid mesh for emergent cases with bowel compromise given risk of infection
- most repairs are now done using tension free techniques – a plug in the hernial defect and a patch over it or patch alone
- observation is acceptable for small asymptomatic inguinal hernias

**Post-Operative Complications**
- recurrence (15-20%)
  - risk factors: recurrent hernia, age >50, smoking, BMI >25, poor pre-operative functional status (ASA ≥3 – see Anesthesia and Perioperative Medicine, A4), associated medical conditions: type 2 DM, hyperlipidemia, immunosuppression, and any comorbid conditions increasing intra-abdominal pressure
  - less common with mesh/"tension-free" repair
- scrotal hematoma (3%)
  - painful scrotal swelling from compromised venous return of testes
- deep bleeding: may enter retroperitoneal space and not be initially apparent
- difficulty voiding
- nerve entrapment
  - ilioinguinal (causes numbness of inner thigh or lateral scrotum)
- genital branch of genitofemoral (in spermatic cord)
- stenosis/occlusion of femoral vein
  - acute leg swelling
- ischemic colitis

Appendicitis

Epidemiology
- 6% of population, M>F
- 80% between 5-35 yr of age

Pathogenesis
- luminal obstruction → bacterial overgrowth → inflammation/swelling → increased pressure → localized ischemia → gangrene/perforation → localized abscess (walled off by omentum) or peritonitis
- etiology
  - children or young adult: hyperplasia of lymphoid follicles, initiated by infection
  - adult: fibrosis/stricture, fecolith, or obstructing neoplasm
  - other causes: parasites or foreign body

Clinical Features
- most reliable feature is progression of signs and symptoms
- low grade fever (38°C), rises if perforation
- abdominal pain then anorexia, N/V
- classic pattern: pain initially periumbilical; constant, dull, poorly localized, then well localized pain over McBurney’s point
  - due to progression of disease from visceral irritation (causing referred pain from structures of the embryonic midgut, including the appendix) to irritation of parietal structures
- signs
  - inferior appendix: McBurney’s sign (see sidebar), Rovsing’s sign (palpation pressure to left abdomen causes McBurney’s point tenderness). McBurney’s sign is present whenever the opening of the appendix at the cecum is directly under McBurney’s point; therefore McBurney’s sign is present even when the appendix is in different locations
  - retrocecal appendix: psoas sign (flexion of hip against resistance or passive hyperextension of hip)
  - pelvic appendix: obturator sign (flexion then external or internal rotation about right hip causes pain)

Complications
- perforation (especially if >24 h duration)
- abscess, phlegmon
- sepsis
**Inflammatory Bowel Disease**

**Investigations**
- laboratory
  - mild leukocytosis with left shift (may have normal WBC counts)
  - higher leukocyte count with perforation
  - β-hCG to rule out ectopic pregnancy
  - urinalysis
- imaging
  - U/S: may visualize appendix, but also helps rule out gynecological causes – overall accuracy 90-94%, can rule in but CANNOT rule out appendicitis (if >6 mm, SENS/SPEC/PPV/PY 98%)
  - CT scan: thick wall, enlarged (>6 mm), wall enhancement, appendicolith, and inflammatory changes – overall accuracy 94-100%, optimal investigation

**Treatment**
- hydrate, correct electrolyte abnormalities
- appendectomy (gold standard)
- laparoscopic vs. open (see sidebar)
- complications: intra-abdominal abscess, appendiceal stump leak
- perioperative antibiotics:
  - cefazolin + metronidazole if uncomplicated peri-operative dose is adequate
- consider treatment with post-operative antibiotics for perforated appendicitis
- for patients who present with an abscess (palpable mass or phlegmon on imaging and often delayed diagnosis with symptoms for >4-5 d), consider radiologic drainage + antibiotics x 14 d ± interval appendectomy once inflammation has resolved = (controversial)
- recent research supports antibiotic only treatment as reasonable for uncomplicated appendicitis, with 10-20% recurrence rates
- colonoscopy in the elderly to rule out other etiology (neoplasm)

**Prognosis**
- mortality rate: 0.08% (non-perforated), 0.5% (perforated appendicitis)
Ulcerative Colitis

- see Gastroenterology, G24

Treatment
- indications for surgical management
  - failure of medical management (including inability to taper steroids)
  - complications: hemorrhage, obstruction, perforation, toxic megacolon (emergency), failure to thrive (children)
  - reduce cancer risk (1-2% risk per yr after 10 yr of disease)
- surgical procedures
  - proctocolectomy and ileal pouch-anal anastomosis (IPAA) ± rectal mucosectomy (operation of choice)
  - proctocolectomy with permanent end ileostomy (if not a candidate for ileoanal procedures)
  - colectomy and IPAA ± rectal mucosectomy
  - in emergency: total colectomy and ileostomy with Hartmann closure of the rectum, rectal preservation

Complications of Treatment
- early: bowel obstruction, transient urinary dysfunction, dehydration (high stoma output), anastomotic leak
- late: stricture, anal fistula/abscess, pouchitis, poor anorectal function, reduced fertility

Prognosis
- mortality: 5% over 10 yr
- total proctocolectomy will eliminate risk of cancer
- perforation of the colon is the leading cause of death from ulcerative colitis

LARGE INTESTINE

Large Bowel Obstruction

Mechanical Large Bowel Obstruction

Etiology

Table 17. Common Causes of LBO

<table>
<thead>
<tr>

<td>Diverticulitis (edema, stricture)</td>
<td>Adhesions</td>
</tr>
<tr>
<td></td>
<td>IBD stricture</td>
<td>Hernias (sigmoid colon in a large groin hernia)</td>
</tr>
</tbody>
</table>

Clinical Features (unique to LBO)
- open loop (10-20%)
  - incompetent ileocecal valve allows relief of colonic pressure as contents reflux into ileum, therefore clinical feature similar to SBO
- closed loop (80-90%) (dangerous)
  - competent ileocecal valve, resulting in proximal and distal occlusions
  - massive colonic distention → increased pressure in cecum → bowel wall ischemia → necrosis → perforation

Treatment
- supportive management: IV fluids, gastrointestinal decompression; 75% require surgical intervention
- surgical correction of obstruction (usually requires resection + temporary diverting colostomy)
- volvulus: initial decompression with flexible sigmoidoscopy, operative reduction or sigmoid resection dependent on severity
- mechanical obstruction: ostomy alone (fecal diversion), colectomy with primary anastomosis or Hartmann procedure. May pursue stenting as bridging (follow with another intervention) or palliation

Prognosis
- overall mortality: 10%
- cecal perforation + feculent peritonitis: 20% mortality

<td>Air throughout small bowel and colon</td>
</tr>
</tbody>
</table>

Functional LBO: Colonic Pseudo-Obstruction (Ogilvie’s Syndrome)

Definition
- acute pseudo-obstruction
- distention of colon without mechanical obstruction in distal colon
- exact mechanism unknown, likely autonomic motor dysregulation → possibly sympathetic deprivation to colon, unopposed parasympathetic tone, and interruption of sacral parasympathetic tone to distal bowel

Associations
- most common: trauma, infection, and cardiac (MI, CHF)
- disability (long-term debilitation, chronic disease, bed-bound nursing home patients, and paraplegia), drugs (narcotic use, laxative abuse, and polypharmacy), other (recent orthopedic or neurosurgery, post-partum, electrolyte abnormalities including hypokalemia, retroperitoneal hematoma, and diffuse carcinomatosis)

Clinical Features
- classically presents with abdominal distention (acute or gradual over 3-7 d)
- abdominal pain, nausea and vomiting, constipation/diarrhea
- watch out for fever, leukocytosis, and presence of peritoneal signs

Investigations
- AXR: cecal dilatation – if diameter ≥12 cm, increased risk of perforation

Treatment
- treat underlying cause
- NPO, NGT
- decompression: rectal tube, colonoscopy, neostigmine (cholinergic drug), surgical decompression (ostomy/resection) uncommon
- surgery (extremely rare): if perforation, ischemia, or failure of conservative management

Prognosis
- most resolve with conservative management
Diverticular Disease

Definitions
- diverticulum: abnormal outpouching from the wall of a hollow organ
- diverticulosis: presence of multiple diverticula
- diverticulitis: inflammation of diverticula
- true (congenital) diverticuli: contain all layers of colonic wall, often right-sided
- false (acquired) diverticuli: contain mucosa and submucosa, often left-sided

Epidemiology
- 5-50% of Western population, lower incidence in non-Western countries, M=F
- prevalence is age dependent: <5% by age 40, 30% by age 60, 65% by age 85
- 95% involve sigmoid colon (site of highest pressure)

Pathogenesis
- risk factors
  - lifestyle: low-fibre diet (predispose to motility abnormalities and higher intraluminal pressure), inactivity, and obesity
  - muscle wall weakness from aging and illness (e.g. Ehlers-Danlos, Marfan’s)
- high intraluminal pressures cause outpouching to occur at point of greatest weakness, most commonly where vasa recta penetrate the circular muscle layer, therefore increased risk of hemorrhage

Clinical Features
- uncomplicated diverticulosis: asymptomatic (70-80%)
- episodic abdominal pain (often LLQ), bloating, flatulence, constipation, diarrhea
- absence of fever/leukocytosis
- no physical exam findings or poorly localized LLQ tenderness
- complications
  - diverticulitis (15-25%): 25% of which are complicated (i.e. abscess, obstruction, perforation, fistula)
  - bleeding (5-15%): PAINLESS rectal bleeding, 30-50% of massive LGIB
  - diverticular colitis (rare): diarrhea, hematochezia, tenesmus, and abdominal pain

Treatment
- uncomplicated diverticulosis: high fibre, education
- diverticular bleed
  - initially workup and treat as any LGIB
  - if hemorrhage does not stop, resect involved region

Diverticulitis

Epidemiology
- 95% left-sided in patients of Western countries, 75% right-sided in Asian populations

Pathogenesis
- erosion of the wall by increased intraluminal pressure or inspissated food particles → inflammation and focal necrosis → micro or macroscopic perforation
- usually mild inflammation with perforation walled off by pericolic fat and mesentery; abscess, fistula, or obstruction can ensue
- poor containment results in free perforation and peritonitis
**Clinical Features**

- Depend on severity of inflammation and whether or not complications are present; hence ranges from asymptomatic to generalized peritonitis
- LLQ pain/tenderness (2/3 of patients) often for several days before admission
- Constipation, diarrhea, N/V, and urinary symptoms (with adjacent inflammation)
- Low-grade fever, mild leukocytosis common, and occult or gross blood in stool rarely coexist with acute diverticulitis
- Complications (25% of cases)
  - Abscess: palpable, tender abdominal mass
  - Fistula: colovesical (most common), colorectal, colovaginal, and colocutaneous
  - Colonic obstruction: due to scarring from repeated inflammation
  - Perforation: generalized peritonitis (feculent vs. purulent)
- Recurrent attacks rarely lead to peritonitis

**Investigations**

- CT scan (test of choice): very useful for assessment of severity and prognosis; usually done with rectal contrast
  - 97% sensitive, 99% specific
  - Increased soft tissue density within pericolic fat secondary to inflammation, diverticula secondary to inflammation, bowel wall thickening, soft tissue mass (pericolic fluid, abscesses), and fistula
  - 10% of diverticulitis cannot be distinguished from carcinoma
- AXR, upright CXR
  - Localized diverticulitis (ileus, thickened wall, SBO, and partial colonic obstruction)
  - Free air may be seen in 30% with perforation and generalized peritonitis
- Elective evaluation: establish extent of disease and rule out other diagnoses (polyps and malignancy) after resolution of acute episode
  - Colonoscopy or barium enema and flexible sigmoidoscopy

**Treatment**

- Uncomplicated: conservative management
- Outpatient: clear fluids only until improvement and antibiotics (e.g. ciprofloxacin and metronidazole) 7-10 d to cover Gram negative rods and anaerobes (e.g. B. fragilis)
- Hospitalize: if severe presentation, inability to tolerate oral intake, significant comorbidities, or fail to improve outpatient management
- Treat with NPO, IVF, and IV antibiotics (e.g. IV ceftriaxone + metronidazole)
- Image-guided (CT) percutaneous drainage of abscesses reduces the urgency of surgical resection in most patients
- Indications for surgery
  - Unstable patient with peritonitis
  - Hinchey stage 3-4 (see Table 19)
  - After 1 attack if immunosuppressed
  - Consider if recurrent episodes of diverticulitis (3 or more), recent trend is toward conservative management of recurrent mild/moderate attacks
  - Complications: perforation, abscess, fistula, obstruction, hemorrhage, inability to rule out colon cancer on endoscopy, or failure of medical management
- Surgical procedures
  - For unstable patient or complex cases: Hartmann procedure
  - Colon resection + colostomy and rectal stump → colostomy reversal in 3-6 mo
  - For more stable patients with Hinchey stage 3 and 4 acute diverticulitis, colonic resection, primary anastomosis + diverting loop ileostomy is becoming more common, with benefits for mortality and morbidity
  - Laparoscopic peritoneal lavage with drain placement near the affected colon, in addition to 4 antibiotics (NO resection) has been proposed for Hinchey stage 3

**Prognosis**

- Mortality rates: 6% for purulent peritonitis, 35% for feculent peritonitis
- Recurrence rates: 13-30% after first attack, 30-50% after second attack

# Colorectal Neoplasms

## Colorectal Polyps

### Definition
- **polyp**: protuberance into the lumen of normally flat colonic mucosa
- **sessile (flat)** or pedunculated (on a stalk)

### Epidemiology
- 30% of the population have polyps by age 50, 40% by age 60, 50% by age 70; M>F

### Clinical Features
- 50% in the rectosigmoid region, 50% are multiple
- usually asymptomatic, do not typically bleed, tenesmus, intestinal obstruction, and mucus
- usually detected during routine endoscopy or familial/high risk screening

### Pathology
- non-neoplastic/non-adenomatous
  - hyperplastic: most common non-neoplastic polyp
  - mucosal polyps: small <5 mm, no clinical significance
  - hamartomas: juvenile polyps (large bowel), Peutz-Jegher syndrome (small bowel)
    - malignant risk due to associated adenomas (large bowel)
    - low malignant potential → most spontaneously regress or autoamputate
  - inflammatory pseudopolyps: associated with IBD, no malignant potential
  - submucosal polyps: lymphoid aggregates, lipomas, leiomyomas, and carcinoids
- neoplastic/adenomatous
  - adenomas: premalignant, considered carcinoma in situ if high grade dysplasia
  - some may contain invasive carcinoma (“malignant polyp” – 3-9%): invasion into submucosa
  - malignant potential related to histological type: villous > tubulovillous > tubular

### Table 20. Characteristics of Tubular vs. Villous Polyps

### Investigations
- colonoscopy with biopsy/resection is the gold standard for diagnosis and treatment of colonic polyps
- CT colonography: increasing in availability; patients still require bowel prep and will require colonoscopy if polyps are identified
- other: flexible sigmoidoscopy if polyps are detected, proceed to colonoscopy for examination of entire bowel and biopsy

### Treatment
- indications: symptoms, malignancy or risk of malignancy (i.e. adenomatous polyps)
- endoscopic removal of entire growth
- indications for segmental resection for malignant polyps: 1) lymphovascular invasion; 2) tumour budding; 3) positive resection margin; 4) poorly differentiated cells; 5) evidence of regional or distant metastases on staging. Most of these cases are usually discussed at multi-disciplinary tumour boards
- follow-up endoscopy:
  - every 5 years: if low-risk polyp (<10 mm tubular adenoma or <10 mm sessile serrated without dysplasia)
  - every 3 years: if high-risk polyp (3-10 tubular adenomas, >10 mm tubular or serrated polyp, adenoma with villous features or high grade dysplasia, or sessile serrated with dysplasia)

## Familial Colon Cancer Syndromes

### FAMILIAL ADENOMATOUS POLYPOSIS

#### Pathogenesis
- autosomal dominant inheritance, mutation in adenomatous polyposis coli (APC) gene
Clinical Features
- hundreds to thousands of colorectal adenomas usually by age 20 (by 40s in attenuated FAP)
- extracolonic manifestations
  - carcinoma of large bowel (i.e. polyps in colon), bile duct, pancreas, stomach, thyroid, adrenal, and small bowel
  - congenital hypertrophy of retinal pigment epithelium presents early in life in 2/3 of patients; 97% sensitivity
  - virtually 100% lifetime risk of colon cancer (because of number of polyps)
- variants
  - Gardner’s syndrome: FAP + extra-intestinal lesions (sebaceous cysts, osteomas, desmoid tumours)
  - Turcot syndrome: FAP + CNS tumours (childhood cerebellar medulloblastoma)

Investigations
- genetic testing (80-95% sensitive, 99-100% specific)
- if no polyposis found: annual flexible sigmoidoscopy from puberty to age 50, then routine screening
- if polyposis or APC gene mutation found: annual colonoscopy and consider surgery; consider upper endoscopy to evaluate for periampullary tumours

Treatment
- surgery indicated by age 17-20
- total proctocolectomy with ileostomy or total colectomy with ileorectal anastomosis
- doxorubicin-based chemotherapy
- NSAIDs for intra-abdominal desmoids

HEREDITARY NON-POLYPOSIS COLORECTAL CANCER – LYNCH SYNDROME

Pathogenesis
- autosomal dominant inheritance, mutation in a DNA mismatch repair gene (MSH2, MSH6, MLH1, PMS2) resulting in microsatellite genomic instability and subsequent mutations
- microsatellite instability account for approximately 15% of all colorectal cancers

Clinical Features
- early age of onset, right > left colon, synchronous and metachronous lesions
- mean age of cancer presentation is 44 yr, lifetime risk 70-80% (M>F)
  - HNPPC I: hereditary site-specific colon cancer
  - HNPPC II: cancer family syndrome – high rates of extracolonic tumours (endometrial, ovarian, hepatobiliary, small bowel)

Diagnosis
- Amsterdam Criteria (“3-2-1 rule”)
  3 or more relatives with verified Lynch syndrome associated cancers, and 1 must be 1st degree relative of the other 2
  2 or more generations involved
  1 case must be diagnosed before 50 yr
  FAP is excluded
- genetic testing (80% sensitive) – colonoscopy mandatory even if negative
  refer for genetic screening individuals who fulfill either the Amsterdam Criteria or the revised Bethesda Criteria
- colonoscopy (starting age 20) annually
- surveillance for extracolonic lesions

Treatment
- total colectomy and ileorectal anastomosis with annual proctoscopy

Colorectal Carcinoma

Epidemiology
- 3rd most common cancer (lung>breast>colon), 2nd most common cause of cancer death

Risk Factors
- most patients have no specific risk factors
- age >50 (dominant risk factor in sporadic cases), mean age is 70
- genetic: FAP, HNPPC, or family history of CRC
- colonic conditions
  - adenomatous polyps (especially if >1 cm, villous, multiple)
  - IBD (especially UC: risk is 1-2%/yr if UC >10 yr)
  - previous colorectal cancer (also gonadal or breast)
  - diet (increased fat, red meat, and decreased fibre) and smoking
  - DM and acromegaly (insulin and IGF-1 are growth factors for colonic mucosal cells)
Pathogenesis
- adenoma-carcinoma sequence; rarely arise de novo

Clinical Features
- often asymptomatic
- hematochezia/melena, abdominal pain, and change in bowel habits
- others: weakness, anemia, weight loss, palpable mass, and obstruction
- 20% patients have distant metastatic disease at time of presentation
  - spread
    - direct extension, lymphatic, and hematogenous (liver most common, lung, bone, and brain; tumour of distal rectum → IVC → lungs)
    - peritoneal seeding: ovary and Blumer’s shelf (pelvic cul-de-sac)
- metastatic lesions confined to the liver can be resected with curative intent
- palliative: if distant spread, local control for hemorrhage or obstruction

Table 21. Clinical Feature of CRC

<table>

</tr>
<tr>
<td>Signs</td>
<td>Fe-deficiency anemia, RLQ mass (10%)</td>
<td>BRBPR, LBO</td>
</tr>
</tbody>
</table>

Investigations
- colonoscopy (best), look for synchronous lesions (3-5% of patients); alternative: air contrast barium enema (‘apple core’ lesion) + sigmoidoscopy
  - if a patient is FOBT +ve, has microcytic anemia, or has change in bowel habits, do colonoscopy
  - laboratory: CBC, urinalysis, liver enzymes, liver function tests, CEA (pre-operative for baseline, >5 ng/mL have worse prognosis)
  - staging: CT chest/abdomen/pelvis; bone scan, CT head only if lesions suspected
  - rectal cancer: pelvic MRI or endorectal U/S to determine T and N stage

Table 22. TNM Classification System for Staging of Colorectal Carcinoma (AJCC/UICC 8th edition)

</tbody>
</table>

Treatment
- colon cancer
  - wide surgical resection of lesion and regional lymphatic drainage; usually colectomy with primary anastomosis
  - curative: wide resection of lesion (5 cm margins) with nodes (>12) and mesentery
  - metastatic lesions confined to the liver can be resected with curative intent
  - palliative: if distant spread, local control for hemorrhage or obstruction
  - care is taken to not spread tumour by unnecessary palpation
  - cancer-bearing portion of colon is removed according to vascular distribution of segment
  - adjuvant chemotherapy (oxaliplatin-based ± capecitabine, fluorouracil) for stage III and is considered in select stage II patients
Other Conditions of the Large Intestine

Angiodysplasia

Definition
vascular malformation: focal submucosal venous dilatation and tortuosity

Clinical Features
- most frequently in right colon of patients >60 yr
- predisposition in end-stage renal disease and von Willebrand disease
- bleeding typically intermittent, rarely massive, and not usually hypotensive (melena, anemia, and occult blood positive stools)

Investigations
- colonoscopy: cherry red spots, branching pattern from central vessel
- angiography: early-filling vein, vascular tuft, and delayed emptying vein; rarely active bleeding
- RBC technetium-99 scan
- barium enema is contraindicated (obscures other x-rays, i.e. angiogram)

Treatment
- none if asymptomatic
- cautery, right hemicolectomy, embolization, vasopressin infusion, sclerotherapy, band ligation, laser, octreotide, and rarely segmental resection if other treatments fail

Volvulus

Definition
- rotation of segment of bowel about its mesenteric axis
- sigmoid (65%), cecum (30%), transverse colon (3%), and splenic flexure (2%)
- 5-10% of large bowel obstruction; 25% of intestinal obstruction during pregnancy

Risk Factors
- age (50% of patients >70 yr: stretching/elongation of bowel with age is a predisposing factor)
- high fibre diet (can cause elongated/redundant colon), chronic constipation, laxative abuse, pregnancy, bedridden, and institutionalization (less frequent evacuation of bowels)

Clinical Features
- symptoms due to bowel obstruction (see Large Bowel Obstruction, GS34) or intestinal ischemia (see Intestinal Ischemia, GS28)
- colicky abdominal pain, persistence of pain between spasms, abdominal distention, and vomiting

Investigations
- AXR (classic findings): “omega”, “bent inner-tube”, “coffee-bean” signs
- barium/Gastrografin® enema: “ace of spades” (or “bird’s beak”) appearance due to funnel-like luminal tapering of lower segment towards volvulus
- sigmoidoscopy or colonoscopy as appropriate
- CT: “whirl pattern” of mesenteric vessels twisting about the volvulus axis

Treatment
- initial supportive management same as initial management for bowel obstruction (see Large Bowel Obstruction, GS34)
• cecum
  • nonsurgical
    • may attempt colonoscopic detorsion and decompression; successful 15-20% of cases
  • surgical
    • right colectomy + ileotransverse colonic anastomosis
• sigmoid
  • nonsurgical
    • decompression by flexible sigmoidoscopy and insertion of rectal tube past obstruction
    • subsequent elective surgery recommended (50-70% recurrence)
  • surgical
    • surgical resection with or without primary anastomosis
    • indications: strangulation, perforation, or unsuccessful endoscopic decompression

### Toxic Megacolon

**Pathogenesis**
- extension of inflammation into smooth muscle layer causing paralysis
- damage to myenteric plexus and electrolyte abnormalities are not consistently found

**Etiology**
- inflammatory bowel disease (ulcerative colitis > Crohn's disease)
- infectious colitis: bacterial (C. difficile, Salmonella, Shigella, and Campylobacter), viral (cytomegalovirus), and parasitic (E. histolytica)

**Clinical Features**
- infectious colitis usually presents for >1 wk before colonic dilatation
- diarrhea ± blood (sudden improvement of diarrhea may signify onset of megacolon)
- abdominal distention, tenderness, ± local/general peritoneal signs (suggests perforation)
- triggers: hypokalemia, constipating agents (opioids, antidepressants, loperamide, and anticholinergics), barium enema, and colonoscopy

**Diagnostic Criteria**
- must have both colitis and systemic manifestations for diagnosis
- radiologic evidence of dilated colon
- three of: fever, HR >120, WBC >10.5, and anemia
- one of: fluid and electrolyte disturbances, hypotension, or altered LOC

**Investigations**
- CBC (leukocytosis with left shift and anemia from bloody diarrhea), electrolytes, elevated CRP, and ESR
- metabolic alkalosis (volume contraction and hypokalemia) and hypoalbuminemia are late findings
- AXR: dilated colon >6 cm (right > transverse > left), loss of haustra
- CT: useful to assess underlying disease

**Treatment**
- NPO, NGT, stop constipating agents, correct fluid and electrolyte abnormalities, and transfusion
- serial AXRs
- broad-spectrum antibiotics (reduce sepsis and anticipate perforation)
- aggressive treatment of underlying disease (e.g. steroids in IBD and metronidazole for C. difficile)
- indications for surgery (50% improve on medical management)
  - worsening or persisting toxicity or dilation after 48-72 h
  - severe hemorrhage, perforation
  - high lactate and WBC, especially for C. difficile
- procedure: subtotal colectomy + end ileostomy (may be temporary with second operation for re-anastomosis later)

**Prognosis**
- 25-30% mortality

### Fistula

**Definition**
- abnormal communication between two epithelialized surfaces (e.g. enterocutaneous, colovesical, aortoenteric, and entero-enteric)

**Etiology**
- foreign object erosion (e.g. gallstone, graft)
- inflammatory states (e.g. infection, IBD [Crohn's > UC], and diverticular disease)
- iatrogenic/surgery (e.g. post-operative anastomotic leak and radiation)
- congenital, trauma
- neoplastic
Investigations
• U/S, CT scan, fistulogram
• measure amount of drainage from fistula

Treatment
• decrease secretion: octreotide/somatostatin/omeprazole
• surgical intervention: dependent upon etiology (for non-closing fistulas); uncertainty of diagnosis

Stomas

Definition
• an opening of the GI tract onto the surface of the abdomen wall
  • stomas can be constructed as either end stomas: the proximal end of the GI tract forms the stoma and the distal end of the GI tract is not part of the stoma
  • loop stomas: a loop of the GI tract is brought up to the skin and the anti-mesenteric surface of the bowel is matured as a stoma
• the proximal and distal GI tract remain in continuity

Ileostomy
• usually positioned in RLQ; ileum is brought through rectus abdominus muscles
• indications: after proctocolectomy for ulcerative colitis, in some cases of Crohn’s disease or familial polyposis
• conventional ileostomy: discharges small quantities of liquid material continuously, appliance (plastic bag attached to a sheet of protective material) required at all times
• continent ileostomy: reservoir is constructed from distal ileum, emptied by inserting catheter into stoma several times a day; rarely used, has mostly been replaced by ileal pouch anal anastomosis

Colostomy
• indications: to decompress an obstructed colon, to protect a distal anastomosis after resection, or to evacuate stool after distal colon or rectum is removed
• colostomies can be done by making an opening in a loop of colon (loop colostomy) or by dividing the colon and bringing out one end (end colostomy)
• most common permanent colostomy is a sigmoid colostomy – expels stool 1/d, no appliance required
• chronic paracolostomy hernia is a common complication

Complications (10%)
• obstruction: herniation, stenosis (skin and abdominal wall), adhesive bands, volvulus
• peri-ileostomy abscess and fistula
• skin irritation
• prolapse or retraction
• diarrhea (excessive output), which may lead to fluid, electrolyte, and nutritional imbalances
### Hemorrhoids

**Etiology**
- Vascular and connective tissue complexes form a plexus of dilated veins (cushion)
- Internal: superior hemorrhoidal veins, above dentate line, portal circulation
- External: inferior hemorrhoidal veins, below dentate line, systemic circulation

**Risk Factors**
- Increased intra-abdominal pressure: chronic constipation, pregnancy, obesity, portal HTN, heavy lifting

**Clinical Features and Treatment**
- **Internal hemorrhoids**
  - Engorged vascular cushions usually at 3, 7, 11 o'clock positions (patient in lithotomy position)
  - Painless rectal bleeding, anemia, prolapson, mucus discharge, pruritus, burning pain, and rectal fullness
    - **1st degree**: bleed but do not prolapse through the anus
    - **2nd degree**: bleed, prolapson with straining, and spontaneous reduction
    - **3rd degree**: bleed, prolapse, and require manual reduction
    - **4th degree**: bleed, permanently prolapsed, and cannot be manually reduced
- **External hemorrhoids**
  - Dilated venules usually mildly symptomatic
    - Pain after bowel movement, associated with poor hygiene
    - Medical treatment: dietary fibre, stool softeners, steroid cream (short course), pramoxine (Anusol®), phlebotonics, and avoid prolonged straining
  - Thrombosed hemorrhoids are very painful
    - Resolve within 2 wk, may leave excess skin = perianal skin tag
    - Treatment: consider surgical decompression within first 48 h of thrombosis, otherwise medical treatment

**Table 23. Signs and Symptoms of Internal vs. External Hemorrhoids**

### Anal Fissures

**Definition**
- Tear of anal canal below dentate line (very sensitive squamous epithelium)
- 90% posterior midline, 10% anterior midline
- If off midline: consider other possible causes such as IBD, STIs, TB, leukemia, or anal carcinoma
- Repetitive injury cycle after first tear
  - Sphincter spasm occurs preventing edges from healing and leads to further tearing
  - Ischemia may ensue and contribute to chronicity

**Etiology**
- Local trauma: constipation, irritation, diarrhea, vaginal delivery, anal intercourse
- Secondary to: Crohn's disease, granulomatous diseases, malignancy, communicable diseases
- Further tearing by internal anal sphincter spasm and hypertonicity

**Clinical Features**
- Acute fissure
  - Very painful bright red bleeding especially after bowel movement, sphincter spasm on limited DRE
  - Treatment is conservative: stool softeners, bulking agents, and sitz baths (heals 90%)
- Chronic fissure (anal ulcer)
  - Triad: fissure, sentinel skin tags, and hypertrophied papillae
  - Treatment
    - Stool softeners, increased fibre intake, and sitz baths
    - Topical nitroglycerin or calcium channel blocker (nifedipine or diltiazem): increases local blood flow, promotes healing, and relieves sphincter spasm
    - Lateral internal anal sphincterotomy (most effective): relieves sphincter spasm to increase blood flow and promote healing; reserved for medically-refractory cases due to 5% chance of fecal incontinence
    - Alternative treatment: botulinum toxin A; inhibits release of acetylcholine (ACh), reducing sphincter spasm
- Always rule out more serious causes (e.g. colon cancer or anal canal cancer) in a person with hemorrhoids and rectal bleeding
- Band ligation can be done as outpatient
- External hemorrhoids will often recur
## Anorectal Abscess

### Definition
- infection typically originating within an obstructed anal crypt which forms an abscess
- common bacterial: *E. coli*, *Proteus*, *Streptococci*, *Staphylococci*, *Bacteroides*, and anaerobes

### Clinical Features
- throbbing pain that may worsen with straining and ambulation
- abscess can spread vertically downward (perianal), vertically upward (suprapelvator), or horizontally (ischiorectal)
- tender perianal/rectal mass on exam

### Treatment
- I&D (lancet incision)/surgical fistulotomy in 50% of cases
- 50% develop anorectal fistulas
- may require antibiotics if diabetic, heart murmur, or cellulitis

---

## Fistula-In-Ano

### Definition
- fistula from anal canal to perianal skin
- an inflammatory tract with internal os at dentate line, external os on skin

### Etiology
- see Fistula, GS42
- same processes that lead to the formation of an anal abscess
- other causes: post-operative, trauma, anal fissure, malignancy, and radiation proctitis

### Clinical Features
- intermittent or constant purulent discharge from perianal opening
- pain
- palpable cord-like tract

### Treatment
- identification
  - internal opening
  - Goodsall’s rule
    - fistulas originating anterior to a transverse line through the anus will have a straight course and exit anteriorly, whereas those originating posterior to the transverse line will begin in the midline and have a curved tract
  - fistulous tract
  - probing or fistulography under anesthesia

---

Recurrent perianal abscesses is associated with Crohn’s disease

Antibiotics are not typically helpful in the treatment of perianal abscesses

Figure 20. Different types of perianal abscesses

Figure 21. Goodsall’s rule

Recurrent perianal abscesses is associated with Crohn’s disease

Antibiotics are not typically helpful in the treatment of perianal abscesses
- surgery
  - fistulotomy: unroof tract from external to internal opening, allow drainage, heals by secondary intention
  - low lying fistula (does not involve external sphincter) → primary fistulotomy
  - high lying fistula (involves external sphincter) → staged fistulotomy with Seton suture placed through tract
    - promotes drainage
    - promotes fibrosis and decreases incidence of incontinence
    - delineates anatomy
    - usually done to spare muscle
  - alternative for high lying fistula → ligation of intersphincteric fistula tract (LIFT) procedure
    - access fistula between sphincter muscles, sparring them

Post-Operative
- sitz baths, irrigation, and packing to ensure healing proceeds from inside to outside

Complications
- recurrence
- rarely fecal incontinence

## Pilonidal Disease

**Definition**
- pilo = hair, nidal = nest; cyst or abscess near or on the intergluteal cleft of the sacrococcygeal area containing hair and skin debris

**Epidemiology**
- occurs most frequently in young men age 15-35 yr; rare in >50 yr

**Etiology**
- obstruction of the hair follicles in this area → formation of cysts, sinuses, or abscesses
- associated with occupations that require prolonged sitting, obesity, and high amounts of body hair

**Clinical Features**
- asymptomatic or chronically itchy until acutely infected, then pain/tenderness, purulent discharge, and increased moisture near the tailbone

**Treatment**
- acute abscess
  - I&D (often performed by primary care doctors)
  - wound packed open
  - 40% develop chronic pilonidal sinuses
- surgery
  - indication: failure of healing after I&D, recurrent disease, or complex disease
  - pilonidal cystotomy: excision of sinus tract and cyst; wound closed by secondary intention, primary closure with tissue flap, or marsupialization (cyst edge sewn to surrounding tissue to leave sinus tract open)

## Rectal Prolapse

**Definition**
- protrusion of some or all of rectal mucosa through external anal sphincter

**Epidemiology**
- extremes of ages: <5 yr and >50 yr
- 85% women

**Etiology**
- lengthened attachment of rectum secondary to constant straining
- 2 types
  1. false/partial/mucosal: protrusion of mucosa only, radial furrows at junction with anal skin; most common type of rectal prolapse in childhood
  2. true/complete (most common): full thickness extrusion of rectal wall, concentric folds in:
    - first degree: prolapse includes mucocutaneous junction
    - second degree: without involvement of mucocutaneous junction
    - third degree (internal intussusception): prolapse is internal, concealed, or occult

**Risk Factors**
- gynecological surgery
- chronic neurologic/psychiatric disorders affecting motility
Clinical Features
- extrusion of mass with increased intra-abdominal pressure
- difficulty in bowel regulation
  - tenesmus, constipation, fecal incontinence
- permanently extruded rectum with excoriation, ulceration, and constant soiling
- may be associated with urinary incontinence or uterine prolapse

Treatment
- Type I
  - conservative: gentle manual reduction of prolapsed area, especially in children
  - mucosectomy with excision of redundant mucosa, mostly in adults
- Type II
  - conservative: reduce if possible
  - surgery: abdominal, perineal, and transsacral approaches

Anal Neoplasms

ANAL CANAL

Squamous Cell Carcinoma of Anal Canal (Above Dentate Line)
- most common tumour of anal canal (75%)
- anus prone to human papillomavirus (HPV) infection, therefore at risk for anal squamous intra-epithelial lesions (ASIL)
  - high grade squamous intra-epithelial lesion (HSIL) and low grade squamous intra-epithelial lesion (LSIL) terminology used
- clinical features: anal bleeding, pain, mass, ulceration, and pruritus; 25% asymptomatic
- treatment: chemotherapy ± radiation ± surgery
- prognosis: 80% 5-yr survival

Malignant Melanoma of Anal Canal
- 3rd most common site for primary malignant melanoma after skin, eyes
- aggressive, distant metastases common at time of diagnosis
- treatment: wide excision or abdominal perineal resection (APR) ± chemoradiation
- prognosis: <5% 5 yr survival

ANAL MARGIN
- clinical features and treatment as for skin tumours elsewhere
- squamous and basal cell carcinoma, Bowen's disease (SCC in situ), and Paget's disease

Liver

---

**Liver Abscesses**

**Etiology**

- **types**
  - pyogenic (bacterial): most common etiology; most often polymicrobial – *E. coli, Klebsiella, Proteus, Strep. milleri*
  - parasitic (amoebic): *Entamoeba histolytica, Echinococcal cyst*
  - fungal: *Candida*
  - sources: direct spread from biliary tract infection, portal spread from GI infection, systemic infection (e.g. endocarditis)

**Clinical Features**

- fever, malaise, chills, anorexia, weight loss, abdominal pain, and nausea
- RUQ tenderness, hepatomegaly, and jaundice

**Investigations**

- CBC (leukocytosis, anemia), LFTs (elevated ALP and hypoalbuminemia common; elevated transaminases and bilirubin variable), blood cultures, INR/PTT, stool cultures, and serology (*E. histolytica* and echinococcus)
- U/S, CXR (right basilar atelectasis/effusion), CT, cyst aspiration with C&S, and MRI

**Treatment**

- treat underlying cause
- pyogenic abscesses generally treated with antibiotic therapy (e.g. ceftriaxone and metronidazole or piperacillin-tazobactam) and U/S- or CT-guided percutaneous drainage or surgical drainage
- consider potential source of sepsis (e.g. biliary source, infected tumour)

**Prognosis**

- overall mortality 15% – higher rate if delay in diagnosis, multiple abscesses, and malnutrition
Neoplasms

BENIGN LIVER NEOPLASMS

Hemangioma (cavernous)
- Pathogenesis: most common benign hepatic tumour; results from malformation of angioblastic fetal tissue
- Risk factors: F:M = 3:1
- Clinical features:
  - Usually small and asymptomatic
  - Consumptive coagulopathy if giant (in children)
- Investigations:
  - Contrast CT (well-demarcated hypodense mass with peripheral enhancement on arterial phase with centripetal filling on delayed phases), U/S (homogenous hypechoic mass), MRI
  - Avoid biopsy: may result in hemorrhage
- Treatment:
  - Usually none

Focal Nodular Hyperplasia
- Pathogenesis: unclear, may be regenerative response to hyperperfusion from anomalous arteries at centre of nodule
- Risk factors: female, age 20-50
- Clinical features: asymptomatic, rarely grows or bleeds, and no malignant potential
- Investigations: central stellate scar on CT scan; MRI, biopsy may be required
- Treatment: may be difficult to distinguish from adenoma/fibrolamellar HCC (malignant potential)
  - If confirmed to be FNH → no treatment required

Adenoma
- Pathogenesis: benign abnormal growth of glandular epithelium
- Risk factors: female, age 20-50, estrogen (OCP, pregnancy), obesity, and type 1 glycogen storage disease
- Clinical features: asymptomatic, rarely grows or bleeds, and no malignant potential
- Investigations: central stellate scar on CT scan; MRI, biopsy may be required
- Treatment:
  - Stop anabolic steroids or OCP
  - Excise, especially if large (>5 cm), due to risk of transformation to HCC and spontaneous rupture/haemorrhage

MALIGNANT LIVER NEOPLASMS

Primary
- Most commonly hepatocellular carcinoma (HCC) and cholangiocarzinomas
- Others include angiosarcoma, hepatoblastoma, and hamangioendothelioma
- Epidemiology: 4th leading cause of cancer death worldwide; 9th in United States; highest in Sub-Saharan Africa and Southeast Asia
- Risk factors:
  - Chronic liver inflammation: cirrhosis from any cause, chronic hepatitis B (inhertently oncogenic) and hepatitis C, hemochromatosis, α1-antitrypsin deficiency, and non-alcoholic steatohepatitis
  - Medications: OCPs (3x increased risk), steroids
  - Smoking, alcohol, betel nuts
  - Chemical carcinogens: aflatoxin, microcystin, and vinyl chloride (associated with angiosarcoma)
- Clinical features:
  - RUQ discomfort and right shoulder pain
  - Jaundice, weakness, weight loss, and fever (if central tumour necrosis)
  - Hepatomegaly, bruit, and hepatic friction rub
  - Ascites with blood (sudden intra-abdominal hemorrhage)
  - Paraneoplastic syndromes: hypoglycemia, hypercalcemia, erythrocytosis, and watery diarrhea
  - Metastasis: lung, bone, brain, and peritoneal seeding
- Investigations:
  - Elevated ALP, bilirubin, and α-fetoprotein (80% of patients)
  - U/S (poorly-defined margins with internal echos), triphasic CT (enhancement on arterial phase and washout on portal venous phase), and MRI
  - Liver enzyme and liver function tests: AST, ALT, ALP, bilirubin, albumin, and INR
- Treatment:
  - Cirrhosis is a relative contraindication to tumour resection due to decreased hepatic reserve
  - Surgical resection (10% of patients have resectable tumours)
  - Liver transplant: may use bridging therapy while awaiting transplant
    - Absolute contraindications: extrahepatic disease and vascular invasion
    - Relative contraindications: dependent on liver transplant protocol based on staging criteria followed by transplant centre
  - Non-surgical: radiofrequency ablation, percutaneous ethanol injection, transcatheter arterial chemoembolization (TACE), chemotherapy (consider sorafenib for HCC; pre-operative chemotherapy for hepatoblastoma is standard of care), and radiotherapy

Staging Criteria for Hepatocellular Carcinoma

Elevated prothrombin activity indicative of systemic or local process
• prognosis
  • 5 yr survival: 18% of all patients; 40-70% of patients undergoing complete resection

Secondary
• metastases to the liver are the most common malignant tumours found in the liver
• etiology
  • GI (colorectal most common), lung, breast, pancreas, ovary, uterus, kidney, gallbladder, and prostate
• treatment
  • depends on the primary cancer site and prognosis
    • often liver metastases are a manifestation of Stage IV disease and chemotherapy is indicated
    • metastasectomy may be appropriate for some cancers
  • hepatic resection of metastatic colorectal liver metastases is standard of care as part of multi-modality treatment that includes chemotherapy if complete resection of the primary cancer and metastases is possible
  • prognosis following liver resection for colorectal metastases is an overall survival of 30-60% at 5 yr

*leading cause in adults, **leading cause in children

Clinical Indications
• early referral for transplant should be considered for all patients with progressive liver disease not responsive to medical therapy, especially:
  • decompensated cirrhosis (ascites, esophageal variceal hemorrhage, spontaneous hepatic encephalopathy, coagulopathy, progressive jaundice, severe fatigue)
  • unresectable primary liver cancers
  • fulminant hepatic failure
  • end-stage liver disease with life expectancy <1 yr and if no other therapy is appropriate
  • suitable HCC not amenable to liver resection

Criteria for Transplantation
• Model for End-Stage Liver Disease (MELD): prognostic model to estimate 3 mo survival following transjugular intrahepatic portosystemic shunt (TIPS) procedure and to prioritize patients awaiting liver transplant; based on creatinine, bilirubin, INR; MELD scores from 6-40 used to prioritize liver allocation
• Child-Turcotte-Pugh Score: classification system to assess the prognosis and the abdominal surgery peri-operative mortality of chronic liver disease and cirrhosis; patient must have ≥7 points (Class B) for transplant evaluation

Contraindications
• active alcohol/substance abuse
• extrahepatic malignancy within 5 yr
• advanced cardiopulmonary disease
• active uncontrolled infection

Post-Operative Complications
• primary non-function (graft failure): urgent re-transplantation is indicated
• acute and chronic rejection, ischemia-reperfusion injury
• vascular: hepatic artery or portal vein thrombosis, IVC obstruction
• biliary complications: fever, increasing bilirubin and ALP
• complications related to immunosuppression: HTN, renal disease, DM, obesity, hyperlipidemia, osteoporosis, malignancy, neurologic complications, infection (leading cause of mortality following transplant)

Prognosis
• patient survival at 1 yr: 85%
• graft survival at 1 yr: >80%, at 5 yr: 60-70%
Cholelithiasis

Definition
- the presence of stones in the gallbladder

Pathogenesis
- imbalance of cholesterol and its solubilizing agents (bile salts and lecithin)
- excess hepatic cholesterol secretion relative to bile salts and lecithin → supersaturated cholesterol which precipitates as gallstones
- North America: cholesterol stones (80%), pigment stones (20%)

Risk Factors
- cholesterol stones
  - obesity
  - age <50
  - estrogens: female, multiparity, OCPs
  - ethnicity: First Nations heritage (especially Pima Indians) > Caucasian > Black
  - terminal ileal resection or disease (e.g. Crohn’s disease)
  - impaired gallbladder emptying: starvation, TPN, DM
  - rapid weight loss: rapid cholesterol mobilization and biliary stasis
- pigment stones (contain calcium bilirubinate)
  - cirrhosis
  - chronic hemolysis
  - biliary stasis (strictures, dilation, biliary infection)
  - protective factors: statins, vitamin C, coffee, exercise

Clinical Feature
- asymptomatic (80%): found incidentally
  - 18% risk of progression to symptomatic gallstone disease within 20 yr
- most do NOT require treatment
- consider cholecystectomy if: increased risk of malignancy (choledochal cysts, Caroli’s disease, porcelain or calcified gallbladder), sickle cell disease, pediatric patient, bariatric surgery, and immunosuppression
- biliary colic (10-25%)

Investigations
- normal bloodwork: CBC, LFTs, liver enzymes, amylase, lipase
- U/S: diagnostic procedure of choice
  - image for signs of inflammation, obstruction, and localization of stones
  - 95% specific for detecting stones
- HIDA scan (cholecintigraphy)
  - used less commonly
- IV technetium-99 radioisotope is excreted into bile, allowing visualization of the biliary tree
  - does not visualize stones; diagnosis based on occluded cystic duct or CBD
Biliary Colic

Pathogenesis
- gallstone transiently impacted in cystic duct, no infection

Clinical Features
- an episode of steady, severe dull pain in the epigastrium or RUQ lasting minutes to hours (<6 h), crescendo-decrescendo pattern
- can present with chest pain, right shoulder tip pain, scapular pain
- N/V
- frequently occurs at night or after fatty meal, not after fasting
- no peritoneal findings, no systemic signs

Investigations
- normal blood work: CBC, electrolytes, liver enzymes, LFTs, bilirubin, amylase
- U/S shows cholelithiasis, may show stone in cystic duct

Treatment
- analgesia, rehydration during colic episode
- elective cholecystectomy (95% success)
  - complications: CBD injury (0.3-0.5%), hollow viscus injury, bile peritonitis, and vessel injury
  - laparoscopic cholecystectomy is the standard of care, no benefit to delaying surgery
  - risk of open cholecystectomy higher in emergency situations

Acute Cholecystitis

Pathogenesis
- inflammation of gallbladder resulting from sustained gallstone impaction in cystic duct or Hartmann's pouch
- no cholelithiasis in 5-10% (see Acalculous Cholecystitis, GS53)

Clinical Features
- often have history of biliary colic
- severe constant (>6 h) epigastric or RUQ pain, anorexia, N/V, and low grade fever (<38.5ºC)
- focal peritoneal findings: Murphy's sign, palpable, and tender gallbladder (in 33%)
- Boas' sign: right subscapular pain

Investigations
- blood work: elevated WBC and left shift, mildly elevated bilirubin, AST, ALT, and ALP
- U/S: 98% sensitive, consider HIDA scan if U/S negative
  - signs: gallbladder wall thickening >4 mm, edema (double-wall sign), gallbladder sludge, pericholecystic fluid, and sonographic Murphy's sign

Complications
- Mirizzi syndrome: extra-luminal compression of CBD/CHD due to large stone in cystic duct
- empyema of gallbladder: suppurative cholecystitis, pus in gallbladder, and sick patient
- emphysematous cholecystitis: bacterial gas present in gallbladder lumen, wall, or pericholecystic space (risk in diabetic patient); organisms involved in secondary infection: E. coli, Klebsiella, Enterococcus
- gangrenous gallbladder (20%), perforation (2%): result in abscess formation or peritonitis
- cholecystoenteric fistula (from repeated attacks of cholecystitis) can lead to gallstone ileus

Treatment
- admit, hydrate, NPO, NGT (if persistent vomiting from associated ileus), analgesics
- antibiotics
  - cefazolin if uncomplicated cholecystitis
- ERCP prior to surgery if CBD stones are present on US
  - MRCP ± ERCP if CBD is markedly dilated or CBD stones suspected
- cholecystectomy
  - early (within 72 h) vs. delayed (after 6 wk)
    - equal morbidity and mortality
    - early cholecystectomy preferred: shorter hospitalization and recovery time, no benefit to delaying surgery
    - emergent OR indicated if high risk, e.g. emphysematous
  - laparoscopic: reduced risk of wound infections, shorter hospital stay, reduced post-operative pain, and increased risk of bile duct injury
  - intra-operative cholangiography (IOC)
    - indications: clarify bile duct anatomy, history of biliary pancreatitis, small stones in gallbladder with a wide cystic duct (>15 mm), and jaundice
  - percutaneous cholecystostomy tube: critically ill or if general anesthetic contraindicated

Early vs. Delayed Laparoscopic Cholecystectomy for Uncomplicated Biliary Colic
Cochrane Database Syst Rev 2013;6:CD007196

Study: To assess the benefits and harms of early vs. delayed laparoscopic cholecystectomy for patients with uncomplicated biliary colic due to gallstones.
Results: One trial with 75 participants, average age 43 y. Early laparoscopic cholecystectomy (<24 h) vs. delayed (mean wait period 4.2 mo). The proportion of serious adverse events was lower in the early vs. delayed group (0% vs. 22.5%, respectively). There was a shorter hospital stay in the early group (MD -1.25 d, 95% CI -2.05 to -0.45) and a shorter operating time in the early group (MD -14.80 min, 95% CI -18.02 to -11.58). There was no difference in the proportion of patients requiring conversion to open cholecystectomy in the two groups.
Conclusion: Early laparoscopic cholecystectomy (<24 h of diagnosis of biliary colic) decreased morbidity during the waiting period for elective laparoscopic cholecystectomy, hospital stay, and operating time.
**Acalculous Cholecystitis**

**Definition**
- acute or chronic cholecystitis in the absence of stones

**Pathogenesis**
- typically due to gallbladder ischemia and stasis

**Risk Factors**
- DM, immunosuppression, ICU admission, trauma patient, TPN, and sepsis

**Clinical Features**
- see Acute Cholecystitis, GS52
- occurs in 10% of cases of acute cholecystitis

**Investigations**
- bloodwork: CBC, electrolytes, LFTs, liver enzymes, amylase, and lipase
- U/S: shows sludge in gallbladder, other U/S features of cholecystitis (see Acute Cholecystitis, GS52)
- CT or HIDA scan

**Treatment**
- IV fluids, pain management
- broad-spectrum antibiotics, cholecystectomy
- if patient unstable → cholecystostomy

**Choledocholithiasis**

**Definition**
- stones in CBD

**Clinical Features**
- 50% asymptomatic
- often have history of biliary colic
- tenderness in RUQ or epigastrum
- acholic stool, dark urine, and fluctuating jaundice
- primary vs. secondary stones
  - primary: formed in bile duct, indicates bile duct pathology (e.g. benign biliary stricture, sclerosing cholangitis, choledochal cyst, and CF)
  - secondary: formed in gallbladder (85% of cases in U.S.)

**Investigations**
- CBC: usually normal; leukocytosis suggests cholangitis
- LFTs: increased AST, ALT early in disease, increased bilirubin (more sensitive), alkaline phosphatase (ALP), gamma glutamyltransferase (GGT) later
- amylase/lipase: to rule out gallstone pancreatitis
- U/S: intra-/extra-hepatic duct dilatation; differential diagnosis is choledochal cyst
- MRCP (90% sensitive)
  - visualization of ampullary region, biliary and pancreatic anatomy
  - non-invasive diagnostic test of choice
- ERCP
  - CBD stones in periamputillary region
  - diagnostic and therapeutic; removal of stones and sphincterotomy possible
  - complications: retained stones, ERCP pancreatitis (1-2%), pancreatic or biliary sepsis

**Percutaneous Transhepatic Cholangiography**
- percutaneous approach to the proximal biliary tree (i.e. intra-hepatic biliary system) via the hepatic parenchyma
- useful for proximal bile duct obstruction or when ERCP fails or not available
- requires prophylactic antibiotics
- contraindications: coagulopathy, ascites, peri/intrahepatic sepsis, and disease of right lower lung or pleura
- complications: bile peritonitis, chylothorax, pneumothorax, biliary sepsis, and hemobilia

**Complications**
- cholangitis, pancreatitis, biliary stricture, and biliary cirrhosis

**Treatment**
- treat with ERCP for CBD stone extraction possibly followed by elective cholecystectomy in 25% of patients
# Acute Cholangitis

## Pathogenesis
- obstruction of CBD leading to biliary stasis, bacterial overgrowth, suppuration, and biliary sepsis – may be life-threatening, especially in elderly

## Etiology
- choledocholithiasis (60%), stricture, neoplasm (pancreatic or biliary), extrinsic compression (pancreatic pseudocyst or pancreatitis), instrumentation of bile ducts (PTC, ERCP), and biliary stent
- organisms: *E. coli*, *Klebsiella*, *Pseudomonas*, *Enterococcus*, *B. fragilis*, and *Proteus*

## Clinical Features
- Charcot's triad: fever, RUQ pain, and jaundice
- Reynold's pentad: fever, RUQ pain, jaundice, shock, and confusion
- may have N/V, abdominal distention, ileus, acholic stools, and tea-coloured urine (elevated direct bilirubin)

## Investigations
- CBC: elevated WBC + left shift
- may have positive blood cultures
- LFTs: obstructive picture (elevated ALP, GGT, and conjugated bilirubin, mild increase in AST, ALT)
- amylase/lipase: rule out pancreatitis
- U/S: intra-/extra-hepatic duct dilatation

## Treatment
- initial: NPO, fluid and electrolyte resuscitation, ± NGT, IV antibiotics (treats 80%)
- biliary decompression
  - ERCP + sphincterotomy: diagnostic and therapeutic
  - PTC with catheter drainage: if ERCP not available or unsuccessful
  - laparotomy with CBD exploration and T-tube placement if above fails
- all patients should also have a cholecystectomy, unless contraindicated

## Prognosis
- suppurative cholangitis mortality rate: 20-30%

# Gallstone Ileus

## Pathogenesis
- repeated inflammation causes a cholecystoenteric fistula (usually duodenal) → large gallstone enters the GI tract (impacting near the ileocecal valve) causing a mechanical bowel obstruction (note: ileus is a misnomer in this context)

## Clinical Features
- crampy abdominal pain, N/V, constipation/obstipation (see Large Bowel Obstruction, GS34)

## Investigations
- AXR: dilated small intestine, air fluid levels, may reveal radiopaque gallstone, and air in biliary tree (pneumobilia) (40%)
- CT: biliary tract air, obstruction, and gallstone in intestine
- Rigler's triad: pneumobilia, small bowel obstruction (partial or complete), and gallstone (usually in right iliac fossa)

## Treatment
- fluid resuscitation, NGT decompression
- surgery: enterolithotomy and removal of stone, inspect small and large bowel for additional proximal stones
- may close fistula surgically or manage expectantly (can resolve spontaneously)
- cholecystectomy is generally not performed
Carcinoma of the Gallbladder

Risk Factors
- chronic symptomatic gallstones (70% of cases), old age, female, gallbladder polyps, porcelain gallbladder, chronic infection (Salmonella, Helicobacter), and abnormal pancreaticobiliary duct junction

Clinical Features
- majority are adenocarcinoma
- may be incidental finding on elective cholecystectomy (~1% of open cholecystectomies on laparoscopic cholecystectomies)
- many patients are asymptomatic until late
- local: non-specific RUQ pain, ± palpable RUQ mass
- Courvoisier’s gallbladder sign: enlarged gallbladder and painless jaundice due to obstruction of CBD, suggestive of gallbladder or pancreatic malignancy
- systemic: jaundice (50%) due to invasion of CBD or compression of CBD by pericholedochal nodes, weight loss, malaise, anorexia
- early local extension to liver, may extend to stomach, duodenum
- early metastasis common to liver, lung, bone

Investigations
- U/S: mural thickening, calcification, loss of interface between gallbladder and liver, and fixed mass
- endoscopic U/S (EUS): good for distinguishing carcinomas from other diagnoses such as polyps, staging, allows sampling of bile for cytology
- abdominal CT: polypoid mass, mural thickening, liver invasion, nodal involvement, and distant metastases
- MRI/MRCP: good for distinguishing benign and malignant polyps

Treatment
- if carcinoma of the gallbladder is suspected pre-operatively, an open cholecystectomy should be considered to avoid tumour seeding of the peritoneal cavity
- confined to mucosa (rare): cholecystectomy
- beyond mucosa: cholecystectomy, en bloc wedge resection of 3-5 cm underlying liver, and dissection of hepato-duodenal lymph nodes

Prognosis
- poor 5 yr survival (20%) as gallbladder carcinoma is often detected late
- better outcomes when detected incidentally following cholecystectomy

Cholangiocarcinoma

Definition
- malignancy of extra- or intrahepatic bile ducts

Risk Factors
- age 50-70, gallstones, ulcerative colitis, primary sclerosing cholangitis, choledochal cyst, Clonorchis sinensis infection (liver fluke), chronic intrahepatic stones (hepatolithiasis)

Clinical Features
- majority are adenocarcinomas
- gradual signs of biliary obstruction: jaundice, pruritus, dark urine, and pale stools
- anorexia, weight loss, RUQ pain, Courvoisier’s sign (if CBD obstructed), hepatomegaly
- early metastases are uncommon, but commonly tumour grows into portal vein or hepatic artery
- Klatskin tumour: cholangiocarcinoma located at bifurcation of common hepatic duct

Investigations
- LFTs show obstructive picture
- U/S, CT: bile ducts usually dilated, but not necessarily
- ERCP or PTC: to determine resectability, for biopsies
- CXR, bone scan: for metastatic workup

Treatment
- if resectable: biliary drainage and wide excision margin
- intra-hepatic lesions: liver resection
  - upper third lesions: duct resection + Roux-en-Y hepaticojejunostomy, ± liver resection
  - middle third lesions (uncommon): duct resection + Roux-en-Y hepaticojejunostomy
  - lower third lesions: Whipple procedure
- unresectable lesions: stent or choledochojejunostomy (surgical bypass)
- chemotherapy ± radiotherapy
- role for transplantation in selected patients with Klatskin tumours

Prognosis
- overall 5 yr survival: localized 30%, regional 24%, distant 2%
Pancreas

Acute Pancreatitis

- see Gastroenterology, G46

GALLSTONE PANCREATITIS (45% of Acute Pancreatitis)

Pathogenesis
- obstruction of pancreatic duct by large or small gallstones and biliary sludge
- backup of pancreatic enzymes can cause autodigestion of the pancreas

Clinical Features (Pancreatitis of Any Etiology)
- pain (epigastric pain radiating to back), N/V, ileus, peritoneal signs, jaundice, and fever
- Inglefinger's sign: pain worse when supine, and better when sitting forward
- may have coexistent cholangitis or pancreatic necrosis
- Ranson's criteria for determining prognosis of acute pancreatitis (see sidebar)
  - APACHE II score for determining prognosis of severe acute pancreatitis
- physical exam may show: tachypnea, tachycardia, hypotension, abdominal distention and tenderness, Cullen's sign, and Grey Turner's sign

Investigations
- lipase (most Sn and Sp), elevated amylase (higher than alcoholic pancreatitis), and leukocytosis
- elevated ALT (>150 IU/L), AST strongly suggest gallstone etiology of pancreatitis
- U/S may show multiple stones (may have passed spontaneously), and edematous pancreas
- CXR, AXR, and CT (if severe to evaluate for complications)

Treatment
- supportive: e.g. NPO, hydration, analgesia, and early enteric nutrition
- antibiotics for severe cases of necrotizing pancreatitis or signs of sepsis
- stone often passes spontaneously (~90%); usually no surgical management in uncomplicated acute pancreatitis
- cholecystectomy during same admission (25-60% recurrence if no surgery)
- may need urgent ERCP + sphincterotomy if CBD stone impacted or cholangitis
- surgical indications in acute pancreatitis (rare):
  - drain placement and debridement for necrotizing pancreatitis if refractory to medical management, if septic, or in ICU without other sources of sepsis

Complications
- local complications
  - acute fluid collections
  - walled-off pancreatic fluid collection/pseudocyst (>4 wk old)
  - abscess/infection, necrosis
- systemic complications
  - splenic/mesenteric/portal vessel thrombosis
  - pancreatic ascites/pancreatic pleural effusion
  - DM (b/c pancreatic & insulin insufficiency)
  - ARDS/sepsis/multiorgan failure
  - coagulopathy/DIC
  - severe hypocalcemia

Chronic Pancreatitis

- see Gastroenterology, G48

Surgical Treatment
- treatment is generally medical
- indications for surgery
  - failure of medical treatment
  - debilitating abdominal pain
  - pseudocyst complications: persistence, hemorrhage, infection, and rupture
  - CBD obstruction (e.g. strictures), and duodenal obstruction
  - pancreatic fistula, variceal hemorrhage secondary to splenic vein obstruction
  - rule out pancreatic cancer (present in 15% of chronic pancreatitis treated surgically)
  - anatomical abnormality causing recurrent pancreatitis
- pre-operative CT and/or ERCP are mandatory to delineate anatomy
- minimally invasive options
  - endoscopic pancreatic duct decompression: less effective than surgery
  - extracorporeal shockwave lithotripsy: if pancreatic duct stones
  - celiac plexus block: lasting benefit in 30% patients, less effective in those <45 yr or with prior pancreatic surgery

Ranson's Criteria

A. At admission
1. Age > 55 yr
2. WBC > 16 x 10^9/L
3. Glucose > 11 mmol/L
4. LDH > 350 IU/L
5. AST > 250 IU/L

B. During initial 48 h
1. Hct drop > 10%
2. BUN rise > 1.8 mmol/L
3. Arterial PO2 < 60 mmHg
4. Base deficit > 4 mmol/L
5. Calcium < 2 mmol/L
6. Fluid sequestration > 6 L

C. Interpretation
≥2 = difficult course
≥3 = high mortality (≥15%)
• surgical options
  • drainage procedures: only effective if ductal system is dilated
  • Puestow procedure (lateral pancreaticojunostomy): improves pain in 80% of patients
  • pancreatectomy: best option in absence of dilated duct
  • Whipple procedure (pancreaticoduodenectomy): proximal disease
  • distal pancreatectomy ± Roux-en-Y pancreaticojunostomy: distal disease
  • total pancreatectomy: refractory disease
• islet cells autotransplantation can be used to control insulin-related morbidity
• denervation of celiac ganglion and splanchic nerves

WALLED-OFF PANCREATIC FLUID COLLECTIONS (PSEUDOCYST)
• localized fluid collections rich in pancreatic enzymes, with a non-epithelialized wall consisting of fibrous and granulation tissue
• complication of chronic and/or acute pancreatitis
• up to 40% resolve spontaneously
• cyst wall must be mature prior to drainage (4-6 wk)
• pseudoaneurysm an absolute contraindication to endoscopic drainage, must embolize first

Treatment
  • if asymptomatic: expectant management
  • if symptomatic: choice of drainage procedure depends on location of fluid collection
    • endoscopic drainage: transmural vs. transpapillary
    • surgical drainage: cystogastrostomy vs. cystoduodenostomy vs. cystojejunostomy
    • percutaneous catheter drainage
    • resection
    • consider biopsy of cyst wall to rule out cystadenocarcinoma

Pancreatic Cancer

Epidemiology
• fourth most common cause of cancer-related mortality in both men and women in Canada
• M:F = 1.3:1, average age: 50-70 yr

Risk Factors
• increased age
• smoking: 2-5x increased risk, most clearly established risk factor
• high fat/low fibre diets
• heavy alcohol use
• obesity
• DM, chronic pancreatitis
• partial gastrectomy
• cholecystectomy
• chemicals: β-naphthylamine, benzidine
• African descent

Clinical Features
• head of the pancreas (70%)
  • weight loss, obstructive jaundice, steatorrhea, and vague constant mid-epigastric pain (often worse at night, may radiate to back)
  • painless jaundice, pruritis, dark urine, pale stools, and Courvoisier’s sign
• body or tail of pancreas (30%)
  • tends to present later and usually inoperable (80% are unresectable at diagnosis)
  • weight loss, vague mid-epigastric pain
  • <10% jaundiced
  • sudden onset DM

Investigations
• serum chemistry is non-specific, can have elevated ALP and high bilirubin
• carbohydrate antigen 19-9 (most useful serum marker of pancreatic cancer)
• U/S, CT (also evaluates metastasis and resectability) ± ERCP, MRI, EUS

Pathology
• ductal adenocarcinoma: most common type (75-80%); exocrine pancreas
• intraductal papillary mucinous neoplasm (IPMN)
• other: pancreatic neuroendocrine tumours (non-functional, insulinoma, gastrinoma, VIPoma, glucagonoma, somatostatinoma), mucinous cystic neoplasm (MCN), acinar cell carcinoma
• see Surgical Endocrinology, GS65 for functional pancreatic neuroendocrine tumours

Treatment
• resectable (10-20% of pancreatic cancer)
  • no involvement of liver, peritoneum, or vasculature (hepatic artery, SMA, SMV, portal vein, IVC, aorta), no distant metastasis
  • Whipple procedure (pancreaticoduodenectomy) for cure <5% mortality
- distal pancreatectomy ± splenectomy, lymphadenectomy if carcinoma of midbody and tail of pancreas
- adjuvant chemotherapy recommended (gemcitabine ± capecitabine, 5-FU/leucovorin)
- locally advanced, borderline resectable
- tumours that abut the SMA, SMV, portal vein, hepatic artery, or celiac artery
- locally advanced, non-resectable (palliative → relieve pain, obstruction)
- encasement of major vascular structures including arteries
- most body/tail tumours are not resectable (due to late presentation)
- relieve biliary/duodenal obstruction with endoscopic stenting or double bypass procedure (choledochoenterostomy + gastroenterostomy)
- palliative chemotherapy (gemcitabine + nab-paclitaxel, FOLFIRINOX) ± radiotherapy

**Prognosis**
- most important poor prognostic indicators are lymph node status, margin status, size >3 cm, perineural invasion (invasion of tumour into microscopic nerves of pancreas)
- overall 5 yr survival for all patients with pancreas cancer is 1%; following surgical resection 5 yr survival is 20%
- median survival for unresectable disease: 3-6 mo if metastatic, 8-12 mo if locally advanced at presentation

**Figure 26. Schematic of Whipple resection showing the resected components**
**Spleen**

### Splenic Trauma

- typically from blunt trauma (especially in people with splenomegaly)
- most common intra-abdominal organ injury in blunt trauma
- may have Kehr’s sign

#### Treatment

- non-operative
  - in stable patients: extended bed rest with serial hematocrit levels, close monitoring for 3-5 d; pediatric guidelines for days of bed rest is grade plus 1 (i.e. grade 3 splenic laceration requires 4 d of bed rest)
  - hemostatic control
  - splenic artery embolization if patient stable and one of: active contrast extravasation, splenic pseudoaneurysm, hemoperitoneum
- operative
  - hemodynamically unstable patients with positive FAST will undergo operative surgical exploration
  - splenorrhaphy (suture of spleen) ± splenic wrapping with hemostatic mesh – if patient hemodynamically stable, patient has stopped bleeding and laceration does not involve hilum
  - partial splenectomy, rarely performed due to risk of recurrent hemorrhage
  - total splenectomy if patient unstable or high-grade injury

### Splenectomy

#### Indications

- splenic trauma (most common reason for splenectomy), hereditary spherocytosis, primary hypersplenism, chronic immune thrombocytopenic purpura (ITP), splenic vein thrombosis causing esophageal varices, splenic abscess, thrombotic thrombocytopenic purpura (TTP), and sickle cell disease
- does not benefit all thrombocytopenic states (e.g. infection, most malignancies involving the bone marrow, drugs/toxins)
- probability of cure of ITP by splenectomy is 60-70%, may be predicted by response to IVIG

#### Complications

- short-term
  - injury to surrounding structures (e.g. gastric wall, tail of pancreas) and their vascular supply
  - post-operative thrombocytoysis, leukocytosis
  - thrombosis of portal, splenic, or mesenteric veins
  - subphrenic abscess
- long-term
  - post-splenectomy sepsis (encapsulated organisms): 4% of splenectomized patients (highest risk in those <16 yr)
  - 50% mortality
  - prophylaxis with vaccinations, ideally 2 wk pre- or post-operative (pneumococcal, H. influenzae, and meningococcus)
  - liberal use of penicillin especially in children <6 yr
    - splenosis: intra-abdominal “seeding” of splenic tissue during removal
    - increased risk of malignancy, DVT, and PE compared to non-splenectomized patients

### Splenic Infarct

#### Pathophysiology

- splenic artery occlusion or oxygen-delivery insufficiency leading to parenchymal ischemia and necrosis
- can occur in sickle cell disease, thromboembolism, myelofibrosis, CML, hypercoagulable states
- patient can be asymptomatic or can have LUQ pain (70%), N/V, fever, chills, and Kehr sign

#### Treatment

- non-operative: close follow-up, analgesia
- indications for splenectomy: complications such as rupture, abscess, persistent pseudocyst, bleeding, or sepsis
Benign Breast Lesions

Three Categories
1. nonproliferative
2. proliferative without atypia
3. atypical hyperplasia

NONPROLIFERATIVE LESIONS
- benign breast condition characterized by fibrous and cystic changes in the breast (fibrocystic changes/disease)
- most common: breast cysts
- other lesions include papillary apocrine change, epithelial-related calcifications and mild hyperplasia of the usual type
- no increased risk of breast cancer
- age 30 to menopause (and after if hormone replacement therapy (HRT) used)
- clinical features
  - breast pain, focal areas of nodularity or cysts often in the upper outer quadrant, frequently bilateral, mobile, varies with menstrual cycle, and nipple discharge (straw-like, brown, or green)
- treatment
  - evaluation of breast mass (U/S, mammography as indicated) and reassurance
  - analgesia (ibuprofen, ASA)
  - for severe symptoms: OCP, danazol, bromocriptine

PROLIFERATIVE LESIONS – WITHOUT ATYPIA

Table 28. Proliferative Lesions - Without Atypia

<table>
<thead>
<tr>
<th>Clinical Features</th>
<th>Diagnosis</th>
<th>Treatment</th>
<th>Risk of Breast Cancer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fibroadenoma</td>
<td>Most common breast tumour in women &lt;30 yr</td>
<td>Nodules: firm, rubbery, discrete, well-circumscribed, non-tender, mobile, hormone-dependent (unlike cysts), needle aspiration yields no fluid</td>
<td>Core or excisional biopsy sometimes required if concerned about malignancy U/S and FNA alone cannot differentiate fibroadenoma from phyllodes tumour</td>
</tr>
<tr>
<td>Intraductal</td>
<td>Solitary intraductal benign polyp</td>
<td>Can present as nipple discharge (most common cause of spontaneous, unilateral, bloody nipple discharge = pathologic nipple discharge), breast mass, nodule on U/S</td>
<td>Surgical excision of involved duct to ensure no atypia</td>
</tr>
<tr>
<td>Papilloma</td>
<td>Usually ductal space</td>
<td>Incidental finding on biopsy of mammographic abnormalities or breast masses</td>
<td>None required</td>
</tr>
<tr>
<td>Usual Ductal</td>
<td>Increased number of cells within the ductal space</td>
<td>Mass or mammographic abnormality</td>
<td>None required</td>
</tr>
<tr>
<td>Hyperplasia</td>
<td>Lobular lesion with increased fibrous tissue and glandular cells</td>
<td>Mass or mammographic abnormality</td>
<td>None required</td>
</tr>
</tbody>
</table>

Levels of Axillary Lymph Nodes
- Level I: lateral to pectoralis minor
- Level II: deep to pectoralis minor
- Level III: medial to pectoralis minor
(higher level of nodal involvement = worse prognosis)

DDx for Breast Mass
Benign
- Fibrocystic changes
- Fibroepithelial lesions (fibroadenoma, most common; benign phyllodes)
- Fat necrosis
- Papilloma/papillomatosis
- Galactoceles
- Duct ectasia
- Ductal/lobular hyperplasia
- Sclerosing adenosis
- Lipoma
- Neurofibroma
- Granulomatous mastitis (e.g. TB, granulomatosis with polyangiitis, sarcoidosis)
- Abscess
- Silicone implant
Malignant
- Breast cancer (likely invasive, DCIS rarely forms a breast mass)
- Malignant phyllodes
- Angiosarcoma (rare)
ATYPICAL HYPERPLASIA
- can involve ducts (atypical ductal hyperplasia) or lobules (atypical lobular hyperplasia)
- cells lose apical-basal orientation
- increased risk of breast cancer
- diagnosis: core or excisional biopsy
- treatment: complete resection, risk modification (avoid exogenous hormones), close follow-up

OTHER LESIONS

Fat Necrosis
- uncommon, result of trauma (may be minor, positive history in only 50%), after breast surgery (i.e. reduction)
- firm, ill-defined mass with skin or nipple retraction, + tenderness
- regress spontaneously, but complete imaging + biopsy to rule out carcinoma

Mammary Duct Ectasia
- obstruction of a subareolar duct (see Obstetrics, OB47)

Abscess
- lactational vs. non-lactational (periductal/subareolar) (see Obstetrics, OB47)

Breast Cancer

Epidemiology
- leading cancer diagnosis in women in North America, 2nd leading cause of cancer mortality in women
- 1 in 8 (12.9% life time risk) women in Canada will be diagnosed with breast cancer in their lifetime
- 1 in 31 women in Canada will die from breast cancer
- all age relative survival is 87%

Risk Factors
- gender (99% female)
- age (83% >50 yr)
- family history of breast cancer and/or prior breast biopsy (regardless of pathology)
- high breast density, nulliparity, first pregnancy >30 yr, menarche <12 yr, or menopause >55 yr
- decreased risk with lactation, early menopause, and early childbirth
- radiation exposure (e.g. mantle radiation for Hodgkin's disease)
- >5 yr HRT use, >10 yr OCP use
- BRCA1 and BRCA2 gene mutations
- alcohol use, obesity, and sedentary lifestyle

Male Breast Cancer (<1%)
- most commonly invasive ductal carcinoma
- often diagnosed at later stages
- stage-for-stage similar prognosis to breast cancer in females
- consider genetic testing: most often hormone receptor positive

Investigations
- mammography
  - indications: screening guidelines (see Family Medicine, FM3)
  - findings indicative of higher risk of malignancy
    - mass that is poorly defined, spiculated border
    - microcalcifications
    - architectural distortion
    - interval mammographic changes
  - normal mammogram does not rule out suspicion of cancer based on clinical findings
- other radiographic studies
  - U/S: differentiate between cystic and solid
  - MRI: high sensitivity, low specificity. Use annual MRI and mammography for patients with 25% lifetime risk of breast cancer
  - galactogram/ductogram (for nipple discharge): identifies lesions in ducts
  - metastatic workup indicated in Stage II-IV disease: bone scan, abdominal U/S, CXR (or CT chest/abdomen/pelvis), CT head (if specific neurological symptoms)
**Diagnostic Procedures**

- "triple test" for diagnosis of breast cancer: clinical breast exam, imaging (U/S for <30 yr, mammography + U/S for >30 yr), pathology (biopsy)
- needle aspiration: for palpable cystic lesions; send fluid for cytology if blood or cyst does not completely resolve
- U/S or mammography guided core needle biopsy (most common)
- excisional biopsy: only performed as second choice to core needle biopsy; should not be done for diagnosis if possible

**Genetic Screening**

- consider testing for BRCA1/2 if:
  - young patient (<35 yr)
  - bilateral breast cancer in patients <50 yr
  - patient diagnosed with breast AND ovarian cancer
  - strong family history of breast/ovarian cancer
  - family history of male breast cancer

**Staging**

- patients are assigned a clinical stage pre-operatively (cTNM); following surgery the pathologic stage is determined (pTNM)
- clinical
  - tumour size by palpation, mammogram, U/S and/or MRI
  - nodal involvement by palpation, imaging
  - metastasis by physical exam, CXR, and abdominal U/S (or CT chest/abdomen/pelvis), bone scan (usually done post-operative if node-positive disease)
- pathological
  - tumour size and type
  - grade: modified Bloom and Richardson score (I to III) – histologic, nuclear, and mitotic grade
  - number of axillary nodes positive for malignancy out of total nodes resected, extranodal extension, and sentinel lymph node biopsy (SLNB) positive/negative
  - tumour biology: estrogen receptor (ER), progesterone receptor (PR), and HER2/neu oncogene status
  - margins: for invasive breast cancer negative margin is sufficient, for DCIS prefer 2 mm margin
  - lymphovascular invasion (LVI)
  - extensive in situ component (EIC): DCIS in surrounding tissue
  - involvement of dermal lymphatics (inflammatory) – automatically Stage IIIb

</table>

**Pathology**

**NON-INVASIVE**

**Ductal Carcinoma in situ (DCIS)**

- proliferation of malignant ductal epithelial cells completely contained within breast ducts, often multifocal
- 80% non-palpable, detected by screening mammogram
- risk of invasive ductal carcinoma in same breast up to 35% in 10 yr
- treatment
  - lumpectomy with wide excision margins + radiation (5-10% risk of invasive cancer)
  - mastectomy if large area of disease, high grade, or multifocal (risk of invasive cancer reduced to 1%)
  - possibly tamoxifen as an adjuvant treatment
  - 99% 5 yr survival
**Lobular Carcinoma in situ (LCIS)**
- neoplastic cells completely contained within breast lobule
- no palpable mass and no mammographic findings; usually incidental finding on breast biopsy for another indication
- LCIS is a risk factor for invasive carcinoma (approximately 1%/yr)
- treatment
  - if diagnosed on core biopsy, excisional biopsy necessary to rule out malignancy
  - if diagnosed on excisional biopsy, wide excision not needed since LCIS often multicentric and not managed as precursor lesion
  - clinical follow-up and surveillance; consider chemoprevention (e.g. tamoxifen)

**INVASIVE**

**Invasive Ductal Carcinoma (most common 80%)**
- originates from ductal epithelium and infiltrates supporting stroma
- characteristics: hard, scirrhus, infiltrating tentacles, and gritty on cross-section
- divided into three grades based on cytologic and architectural features: well differentiated (grade 1), moderately differentiated (grade 2), poorly differentiated (grade 3)

**Invasive Lobular Carcinoma (8-10%)**
- originates from lobular epithelium, 20% bilateral
- subtle thickening originating from lobes/lobules; usually positive for estrogen and progesterone receptors
- harder to detect on mammography due to lack of microcalcifications (may benefit from MRI)

**Paget’s Disease (1-3%)**
- ductal carcinoma that invades nipple with scaling, and eczematoid lesion

**Inflammatory Carcinoma (1-3%)**
- most aggressive form of breast cancer
- ductal carcinoma that grows in nests (vs. solid tumour); invades and blocks dermal lymphatics
- clinical features: erythema, skin edema, warm, swollen, and tender breast ± lump, nipple changes
- peau d’orange indicates advanced disease (IIIb-IV)

**Sarcomas: rare**
- most commonly phyllodes tumour, a variant of fibroadenoma with potential for malignancy
- can also be angiosarcomas – after previous radiation

**Lymphoma: rare**

**Other**
- papillary, medullary, mucinous, and tubular cancers
- generally better prognosis

**Treatment**

</tbody>
</table>

BCS = breast conserving surgery; SLNB = sentinel lymph node biopsy

*If no reason to select mastectomy, the choice between BCS + radiotherapy and mastectomy can be made according to patient’s preference since choice of local treatment does not significantly affect survival if local control is achieved.
 PRIMARY SURGICAL TREATMENT

Breast Conservation Surgery (BCS)
- Lumpectomy must be combined with radiation for survival equivalent to mastectomy
- Contraindications include
  - High risk of local recurrence (e.g., extensive malignant-type calcifications on mammogram), and multifocal primary tumors
  - Failure to obtain tumour-free margins after re-excision
  - Not suitable for radiation therapy (pregnancy, previous radiation, and collagen vascular disease)
  - Large tumour size relative to breast

Mastectomy
- Radical mastectomy (rare): removes all breast tissue, skin, pectoralis muscle, and axillary nodes
- Modified radical mastectomy (MRM): removes all breast tissue, skin, and axillary nodes
- Simple mastectomy: removes all breast tissue and skin
  - See Plastic Surgery PL37 for breast reconstruction

Sentinel Lymph Node Biopsy (SLNB)
- Performed in women with clinically node-negative invasive breast cancer and those with extensive DCIS who are undergoing mastectomy
- Patients with clinically suspicious nodes should get U/S + FNA prior to decision to proceed with SLNB
- Technetium-99 ± blue dye injected at tumour site prior to surgery to identify sentinel node(s)
- Intra-operative frozen section evaluated can be considered
- Proceed with ALND if >3 positive nodes, with 1-3 nodes whole breast radiation therapy may be alternative
- 5% false negative rate

Axillary Lymph Node Dissection (ALND)
- Perform in all patients with pathologic confirmation of nodal involvement (including positive SLNB as above)
- Side effects: risk of arm lymphedema (10-15%) especially if getting radiation therapy, decreased arm sensation, and shoulder pain

ADJUVANT/NEOADJUVANT

Radiation
- Indications
  - Decrease risk of local recurrence; almost always used after BCS, sometimes after mastectomy
  - Inoperable locally advanced cancer
  - Axillary nodal radiation may be added if nodal involvement

Hormonal
- Indications
  - ER positive plus node-positive or high-risk node-negative
  - Selective estrogen receptor modulators (SERM) if premenopausal (e.g., tamoxifen) or aromatase inhibitors if postmenopausal (e.g., anastrozole); optimal duration 5-10 yr
  - Other options include ovarian ablation (e.g., goserelin/GnRH agonist, oophorectomy), progestins (e.g., megestrol acetate), and androgens (e.g., fluoxymesterone)
  - Palliation for metastatic disease

Chemotherapy
- Indications
  - ER negative plus node-positive or high-risk node-negative
  - Triple-negative disease (ER/PR and HER2-negative) - more common in younger and African-American women
  - ER positive and young age
  - Stage I disease at high risk of recurrence (high grade, lymphovascular invasion)
  - Palliation for metastatic disease
  - For HER2 positive breast cancer, add trastuzumab ± pertuzumab to the chemotherapy regimen

FOLLOW-UP

Post-Treatment Follow-Up
- Assessment and physical exam q3-6mo x 3 yr, q6-12mo x 2 yr, and annually thereafter
- Following BCS mammography q6-12mo; can reduce to annual once stable, no other routine imaging unless clinically indicated
- Women who receive tamoxifen should have regular gynecologic follow-up (increased risk of endometrial cancer)
Local/Regional Recurrence
- recurrence in treated breast or ipsilateral axilla
- 1% per yr up to maximum of 15% risk of developing contralateral malignancy
- 5x increased risk of developing metastases

Metastasis
- bone > lungs > pleura > liver > brain
- treatment is palliative: hormone therapy, chemotherapy, radiation
- overall survival of metastatic breast cancer is 36-60 mo

Thyroid and Parathyroid
- see Endocrinology, E21

Thyroidectomy
- indications: thyroid cancer, large or symptomatic thyroid goitre, toxic nodules, or some patients with Graves' disease (not candidates for RAI)
- pre-operative workup: thyroid U/S for thyroid nodules, FNA for nodules ≥1 cm with suspicious U/S features or for most nodules ≥1.5 cm with low suspicion U/S features, and CT neck for preoperative staging when advanced disease is suspected
- complications
  - lobectomy: recurrent laryngeal nerve palsy (hoarseness or swallowing issues), neck hematoma
  - total thyroidectomy: same as above plus hypoparathyroidism/hypocalcemia, bilateral RLN palsy (requiring tracheostomy)
  - 20-60% of patients need thyroxine after lobectomy and 100% need thyroxine after total thyroidectomy

Parathyroidectomy
- indications: symptomatic primary hyperparathyroidism due to effects of PTH on bone or kidneys, asymptomatic primary hyperparathyroidism with specific laboratory criteria (elevated serum Ca++, marked hypercalcuria, Cr clearance <30% normal, bone density reduction with T score <2.5, <50 yr)
- contraindications: familial hypocalciuric hypercalcemia
- pre-operative workup: 99mTc sestamibi scanning, ± SPECT or CT, U/S
- complications: recurrent/superior laryngeal nerve injury, post-operative hypocalcemia, infection, and bleeding

Adrenal Gland
- see Endocrinology, E30
- functional anatomy
  - cortex: glomerulosa (mineralocorticoids), fasciculata (glucocorticoids), and reticularis (sex steroids)
  - medulla: catecholamines (epinephrine, norepinephrine)
- types of adrenal tumours: functional (e.g. Cushing's syndrome, Conn's syndrome, pheochromocytoma) or non-functional

INCIDENTALOMA
- adrenal mass discovered by investigation of unrelated symptoms

Epidemiology
- benign adenoma (38%) > metastases to adrenal (22%) >> cyst, carcinoma, pheochromocytoma, neuroblastoma
- metastasis to adrenal gland from: lung > breast, colon, lymphoma, melanoma, and kidney
- peak incidence of carcinoma: females age 50-60, risk decreases with increasing age and male gender

Investigations
- MRI, CT: size >6 cm is best predictor of primary adrenal carcinoma (92% are >6 cm)
- functional studies
  - pheochromocytoma: plasma metanephrines (highly specific and sensitive). If not available, 24 h urine catecholamines
  - Cushing's: 24 h urine cortisol or 1 mg overnight dexamethasone suppression test
  - aldosteronoma: electrolytes, aldosterone, plasma renin activity level, saline suppression test if appropriate
  - adrenal androgens: 17-OH progesterone and dehydroepiandrosterone (DHEAS)
- FNA biopsy: usually not recommended. May be helpful in situations when diagnostic uncertainty for metastasis
Treatment
- functional tumour: resect
- non-functional tumour
  - >4 cm: resect
  - <4 cm: follow-up imaging in 6-12 mo, resect if >1 cm enlargement

Pancreas

INSULINOMA
- tumour that secretes insulin
- most common pancreatic endocrine neoplasm; 10% associated with MEN1 syndrome

Clinical Features
- Whipple's triad
- palpitations, trembling, diaphoresis, confusion, seizure, and personality changes

Investigations
- blood work: decreased serum glucose and increased serum insulin and C-peptide, pro-insulin
- U/S, CT: insulinomas evenly distributed throughout head, body, tail of pancreas

Treatment
- only 10% are malignant
- enucleation of solitary insulinomas may be done endoscopically
- tumours >2 cm located close to the pancreatic duct may require pancreatectomy or pancreaticoduodenectomy

GASTRINOMA
- tumour secreting gastrin; cause of Zollinger-Ellison syndrome

Clinical Features
- abdominal pain, PUD, severe esophagitis
- multiple ulcers in atypical locations refractory to antacid therapy

Investigations
- blood work: serum gastrin levels (usually >1000 pg/mL), secretin stimulation test
- U/S, CT: 70-90% found in Passaro's triangle (head of pancreas medially, 2nd portion of duodenum inferiorly, and the confluence of the cystic and CBD superiorly)
- octreotide scintigraphy scan

Treatment
- 50% are malignant
- surgical resection of tumour dependent on location
- non-surgical treatment: chemotherapy, somatostatin analogues, interferon, and chemoembolization
- if inoperable, vagotomy can be performed for symptomatic control

VASOACTIVE INTESTINAL PEPTIDE-SECRETING TUMOUR
- tumour secreting VIP; commonly located in the distal pancreas and most are malignant when diagnosed

Clinical Features
- severe watery diarrhea causing dehydration, weakness, and electrolyte imbalance

Investigations
- blood work: serum VIP levels
- U/S, CT

Treatment
- somatostatin analogues
- surgical resection/palliative debulking
Hydrocele (see Urology, U31)

### Inguinal Hernias

<table>
<thead>
<tr>
<th>Condition</th>
<th>Epidemiology and Risk Factors</th>
<th>Pathophysiology</th>
<th>Clinical Features and History</th>
<th>Physical Exam</th>
<th>Investigations</th>
<th>Treatment</th>
<th>Prognosis</th>
</tr>
</thead>
<tbody>
<tr>
<td>Inguinal Hernias</td>
<td>5% of all term newborns 2x risk and more likely bilateral if pre-term M:F = 4:1 Low birth weight increases risk U/S inguinal hernias will become incarcerated if patient is &lt;1 yr Incarceration is more common in females Associated with other conditions: androgen insensitivity, connective tissue diseases</td>
<td>All infant hernias are indirect; descent of intra-abdominal contents through the internal inguinal ring through a patent tunica vaginalis Inguinal hernia can be reducible, incarcerated (incarcerated), or strangulated</td>
<td>Most common presentation: painless intermittent mass in groin, may also note extension into scrotum (scrotal mass in absence of inguinal mass is a hydrocele) If incarcerated: tender, vomiting, firm mass, erythema then cyanosis of mass may be noted</td>
<td>Palpate for “bag of worms” suggests possible testicular varicocele Biannual testicular exam + palpation along inguinal canal to evaluate for any masses “5K sign” – palpable thickening of cord Mass palpated at external inguinal ring and reducible through inguinal canal into abdomen Must always try reduction to confirm that hernia is not incarcerated</td>
<td>Physical exam is gold standard U/S only if physical exam uncertain (e.g. in small infants where exam can be difficult)</td>
<td>Manual reduction – in the ER to relieve acute symptoms (then repair) For reducible hernia: repair within a few weeks (if &lt;1 yr) vs. elective repair (if &gt;1 yr) For incarcerated hernia: repair immediately (emergency) Hemorrhage – definitive treatment by reduction of herniated contents and high ligation of sac for indirect hernias Laparoscopic or open techniques</td>
<td>Risk of recurrence after surgical reduction &lt;3% but higher if repair done in premature infants or if hernia was incarcerated/strangulated at repair</td>
</tr>
</tbody>
</table>

---

All inguinal hernias of infancy and childhood require repair at the earliest convenience; emergent repair if incarcerated/strangled
Skin Lesions

- see Dermatology, D5; Emergency Medicine, ER43; Plastic Surgery, PL5

Common Medications

**Antiemetics**
- dimenhydrinate (Gravol®) 25-50 mg PO/IV/IM q4-6h prn
- prochlorperazine (Stemetil®) 5-10 mg PO/IV/IM bid-tid prn
- metoclopramide (Maxeran®) 10 mg IV/IM q3-4h prn, 10-15 mg PO qid (30 min before meals and qhs)
- ondansetron (Zofran®) 4-8 mg PO q8h prn
- granisetron (Kytri®) 1 mg PO bid (for nausea from chemotherapy/radiation)

**Analgesics**
- acetaminophen ± codeine (Tylenol® #3/plain) 1-2 tabs q4-6h PO/PR prn
- hydromorphone 1-2 tabs PO q4h prn, 0.5-2 mg IV q3-4h prn
- bupropfen 200-400 mg PO q4-6h prn
- morphine 2.5-10 mg IM/SC q4-6h prn + 1-2 mg IV q1h prn for breakthrough
- ketorolac (Toradol®) 30-60 mg IV/IM q6h prn
- acetaminophen/oxycodone (Percocet®) 325/5 mg, 1-2 tabs PO q4-6h prn

**DVT Prophylaxis**
- heparin 5000 units SC bid, if cancer patient then heparin 5000 units SC tid/bid
- dalteparin (Fragmin®) 5000 units SC daily
- enoxaparin (Lovenox®) 40 mg SC daily

**Antidiarrheals**
- loperamide (Imodium®) 4 mg PO initially, then 2 mg PO after each loose stool up to 16 mg/d
- diphenoxylate + atropine (Lomotil®) 2 tabs/10 mL PO qid

**Laxatives**
- sennosides (Senokot®) 1-2 tabs qhs
- docusate sodium (Colace®) 100 mg PO bid
- glycerine suppository 1 tab PR prn
- lactulose 15-30 mL PO qid prn
- milk of magnesia (MOM) 30-60 mL PO qid prn
- bisacodyl (Dulcolax®) 10-15 mg PO prn

**Sedatives**
- zopiclone (Imovane®) 5-7.5 mg PO qhs prn
- lorazepam (Ativan®) 0.5-2 mg PO/SL qhs prn

**Antibiotics**
- cefazolin (Ancef®) 1 g IV on call to OR or q6h – GP except Enterococcus, GN only E. coli, Klebsiella, and Proteus
- cefalexin (Keflex®) 250-500 mg PO qd – Listeria, GP except Enterococcus, GN only E. coli, Klebsiella, and Proteus
- ceftriaxone 1-2 g IM/IV q24h – broad coverage including Pseudomonas
- ampicillin 1-2 g IV q4-6h – Listeria, GP (Enterococcus) except Streptococcus and E. coli, oral anaerobes except Bacteroides
- gentamicin 3-5 mg/kg/d IM/IV divided q8h; monitor creatinine, gentamicin levels – GN including Pseudomonas
- ciprofloxacin 400 mg IV q12h, 500 mg PO bid – GN including Pseudomonas
- metronidazole (Flagyl®) 500 mg PO/IV bid (500 mg PO tid for C. difficile) – anaerobes
- clindamycin 600-900 mg IV q8h, 150-400 mg PO qd – GP except Enterococcus, anaerobes
- piperacillin/tazobactam 4.5 mg IV q6h – GP, GN, and anaerobes
- vancomycin 1g IV q12h – GP and MRSA
- sulfamethoxazole/trimethoprim DS (Septra®) PO bid – GP, GN including Nocardia

**Over-the-Counter Medications**
- bismuth subsalicylate (Pepto-Bismol®) 2 tabs or 30 mL PO q30min-1h up to 8 doses/d – side effects: black stools, risk of Reye's syndrome in children
- ASA + citrate + bicarbonate (Alka-Seltzer®) 2 tabs in 4 oz water PO q4h prn, max 8 tabs
- aluminum hydroxide + magnesium hydroxide (Maalox®) 10-20 mL or 1-4 tabs PO prn
- calcium carbonate (Tums®) 1-3 g PO q6h prn
- calcium carbonate and magnesium hydroxide (Rolaids®) 2-4 tabs PO q6h prn, max 12 tabs/d

Definition

- Major categories of impairment that develop with old age and affect the physical, mental, and social domains of the elderly, usually due to many predisposing and precipitating factors rather than a single cause.
Frailty

Definition
- frailty: clinically-recognizable state of decreased reserve in older adults with increased vulnerability to acute stressors resulting from functional decline across multiple physiologic systems
- functional decline: progressive limitation in the ability to carry out basic functional activities

Clinical Frailty Scale
Shown to predict death and need for institution care.

Models of Frailty

Physical Frailty (PF) Phenotype (Fried et al.)
- Frail = 1 or more criteria; at-risk or pre-frail = 1 or 2 criteria
  1. Shrinking: unintentional weight loss (baseline: >10 lbs or 5% total body weight lost in prior year)
  2. Weakness: grip strength in lowest 20% (by gender, BMI)
  3. Poor endurance: as indicated by self-report of exhaustion
  4. Slowness: walking time/15 feet in slowest 20% (by gender, height)
  5. Low activity: kcals/wk in lowest 20% (males: <383 kcals/wk, females: <270 kcals/wk)

Cumulative Deficit Approach (Rockwood et al.)
- balance between assets (e.g. health, attitudes, resources, caregiver) and deficits (e.g. illness, disability, dependence, caregiver burden) that determines whether a person can maintain independence in the community
- Frailty Index = number of deficits present/number of deficits possible

Etiology
- multifactorial: dysregulated immune, endocrine, stress, and energy response systems lead to development of clinical frailty

Table 2: Etiologies of Frailty

<table>
<thead>
<tr>
<th>Etiology</th>
<th>Mechanism</th>
</tr>
</thead>
<tbody>
<tr>
<td>Physiologic Changes with Aging</td>
<td>Sarcomenia (age-related loss of skeletal muscle and strength), decreased mass and increased stiffness of organs, decreased reserve capacity of systems</td>
</tr>
<tr>
<td>Immune System</td>
<td>Elevated levels of circulating interleukin-6, reactive protein, white blood cells, and monocytes associated with skeletal muscle decline</td>
</tr>
<tr>
<td>Endocrine System</td>
<td>Decreased skeletal muscle mass via: Decreased growth hormone and IGF-1, Increased cortisol levels, Decreased DHEA-S, Decreased 25 (OH) vitamin D</td>
</tr>
</tbody>
</table>

Dysregulated Stress Dysregulation of autonomic nervous system
- Age-related changes in renin-angiotensin system and mitochondria likely impact sarcopenia and inflammation
Evidence-based Approach to the Frail Older Patient

- Comprehensive Geriatric Assessment
  - includes: Past Medical History, Medications, Allergies, Social History, Function, Physical Exam, and Geriatric Review of Systems (cognition, mood, sleep, pain, nutrition, falls, continence, vision/hearing, skin, and safety)
  - interdisciplinary primary care
  - pharmacological care and medication optimization
  - management of geriatric syndromes (e.g. falls, cognitive impairment, incontinence)
  - caregiver support

Delirium

- see Psychiatry, PS22 and Neurology, N20

Definition

- acute and potentially reversible disturbance in cognition, attention, or level of consciousness
- screened using the Confusion Assessment Method: delirium likely if 1 + 2 and either 3 or 4 are present
  1: acute onset and fluctuating course
  2: inattention
  3: disorganized thinking
  4: altered level of consciousness

Differential Diagnosis

- 3Ds (dementia, delirium, depression) can present with overlapping cognitive changes

Work-Up

- work-up is not universal, and depends on possible causes based on history and physical exam:
  - Drugs: medication review
  - Infection, Infarction, Inflammation: CBC, urinalysis, urine culture, blood culture, chest x-ray, ECG/troponin
  - Metabolic: basic and extended electrolytes, Vit B12, TSH, LFT, toxicology screen
  - Structural: neurologic exam, CT head

Delirium Prevention in Elderly

- ensure optimal vision and hearing to support orientation (e.g. appropriate eyewear and hearing aids)
- provide adequate nutrition and hydration (up in chair to eat and drink whenever feasible)
- encourage regular mobilization to build and maintain strength, balance, and endurance
- avoid unnecessary medications and monitor for drug interactions
- avoid bladder catheterization
- ensure adequate sleep at night and wakefulness during the day

Falls

Definition
- an event resulting in a person coming to rest inadvertently on a lower level, other than as a consequence of sudden paralysis, epileptic seizure, or overwhelming external force

Epidemiology
- 30–40% of people >65 yr old and ~50% of people >80 yr old fall each year
- equally common between men and women, but more likely to result in injury in women and death in men
- falls are the leading cause of death from injury in persons ≥65 yr
- 25% associated with serious injuries (e.g. hip fracture, head injury, bruises, laceration)
- between 25–75% do not recover to previous level of ADL function after injurious falls

Etiology
- intrinsic factors
  - age-related changes and diseases associated with aging: musculoskeletal (arthritis, muscle weakness), sensory (visual, proprioceptive, vestibular), cognitive (depression, dementia, delirium, anxiety), cardiovascular (CAD, arrhythmia, MI, low BP), neurologic (stroke, decreased LOC, gait disturbances/ataxia), metabolic (glucose, electrolytes)
  - orthostatic/syncopal
  - acute illness, exacerbation of chronic illness
- extrinsic factors
  - environmental (e.g. home layout, slippery surfaces, overcrowding, new environments)
  - side effects of medications, polypharmacy (>4 medications), and substance abuse (e.g. alcohol)
- situational factors
  - activities (e.g. rushing to the toilet, walking while distracted)

History and Physical Exam
- history: previous falls and/or gait instability, inquire about intrinsic, extrinsic and situational factors, associated symptoms, loss of consciousness, medication and alcohol use, change in medications
- have a witness present if possible for interview
- physical exam: orthostatic blood pressure, cardiac, visual acuity, examination of feet and footwear, Performance-Oriented Assessment of Mobility, Timed Up-and-Go Test, MSK, neurologic

Investigations
- comprehensive geriatric assessment to identify all potential causes
- CBC, electrolytes, BUN, creatinine, glucose, Ca²⁺, TSH, B12, urinalysis, cardiac enzymes, ECG, CT head (as directed by history and physical), coagulation profile
- bone densitometry (DEXA) for osteoporosis screening in all women and men >65 yr old

Interventions
- multidisciplinary, multifactorial, health, and environmental risk factor assessment and intervention programs in the community
- muscle strengthening, balance retraining (e.g. Tai Chi), and group exercise programs
- home hazard assessment and modification (e.g. remove loose rugs and tripping hazards, add shower bars and stair railing, improve lighting)
- prescription of vitamin D 1000 IU daily if vitamin D stores are low
- tapering or gradual discontinuation of psychotropic medication
- postural hypotension, heart rate, and rhythm abnormalities management
- eyesight (cataract surgery) and footwear optimization
- compression socks if venous stasis edema

Malnutrition

Definition
- no uniformly accepted definition of malnutrition in older adults. Some commonly used definitions include the following:
  - involuntary weight loss (community: ≥2% over 1 mo, >10 lbs over 6 mo, or ≥4% over 1 yr; nursing home: ≥5% over 1 mo, ≥10% over 180 d)
  - hypoalbuminemia (community: ≤38 g/L; hospital: ≤35 g/L), hypocholesterolemia (<4.1 mmol/L)
  - other features include: insufficient energy intake, loss of muscle mass, fluid accumulation (e.g. edema), loss of subcutaneous fat, decreased hand-grip function

Etiology
- nutritional
  - decreased assimilation: impaired transit, malabsorption, malnutrition
  - decreased intake: financial, psychiatric (depression), cognitive deficits, anorexia associated with chronic disease, functional deficits (e.g. difficulty shopping, preparing meals or feeding oneself due to functional impairment)
• stress: acute or chronic illness/infection, chronic inflammation, abdominal pain
• mechanical: dental problems, dysphagia
• age-related changes: appetite dysregulation, decreased thirst
• mixed: increased energy demands (e.g. hyperthyroidism), abnormal metabolism, protein-losing enteropathy

Clinical Features
• history
  ▪ weight loss in 6 mo prior to examination
  ▪ recent or chronic illness
  ▪ constitutional symptoms (e.g. recent weight loss)
  ▪ dietary intake in relation to usual pattern
  ▪ depression, GI symptoms (anorexia, nausea, vomiting, diarrhea)
  ▪ functional disability: impaired ADLs and IADLs
  ▪ social factors: economic barriers, dental problems, and living situation (e.g. living alone)
• physical exam
  ▪ BMI <23.5 in males, <22 in females should raise concern
  ▪ muscle wasting, temporal wasting, presence of triceps skin fold
  ▪ loss of subcutaneous fat
  ▪ ankle or sacral edema, ascites
  ▪ assess cognition

Investigations
• CBC, electrolytes, Ca²⁺/albumin, Mg²⁺, PO₄³⁻, creatinine, LFTs (INR, bilirubin), B12, folate, TSH, lipid profile
• if indicated by assessment, can consider urinalysis, ESR, CXR

Treatment
• direct treatment at underlying causes
• dietary modification: high calorie foods, oral nutritional supplementation: patient specific meal replacement products (e.g. Ensure⁺, Glucerna⁺, Nepro⁺), vitamins/minerals (e.g. B12, calcium, vitamin D)
• referral: speech language pathologist, nutritionist

Constipation

• see Gastroenterology, G27

Definition
• Rome IV Diagnostic Criteria: straining, hard stools, sensation of incomplete evacuation, use of digital maneuvers, and/or sensation of anorectal obstruction/blockage with 25% of bowel movements and <3 bowel movements per wk. The criteria must be fulfilled for the last 3 mo with symptom onset ≥ 6 mo prior to diagnosis

Epidemiology
• chronic constipation increases with age (up to 1/3 of patients >65 yr experience constipation and 1/2 of patients >80 yr)
• in the elderly, chronic constipation may present as fecal impaction

Pathophysiology
• impaired rectal sensation (increased rectal distention required to stimulate the urge to defecate)
• colorectal dysmotility

Treatment
• non-pharmacological
  ▪ increase fibre intake (note: bulking agents, e.g. psyllium, Metamucil, may worsen constipation)
  ▪ ensure adequate fluid intake
  ▪ increase physical activity
• pharmacological
  ▪ discourage chronic laxative use
  ▪ review medication regime, reduce dosages or substitute
• see Common Medications, GM14
Incontinence

Fecal Incontinence

Definition
- involuntary or inappropriate passing of feces that impacts social functioning or hygiene
- severity can range from unintentional flatus to the complete evacuation of bowel contents
- there are three subtypes:
  1. passive incontinence: involuntary discharge of stool or gas without awareness
  2. urge incontinence: discharge of fecal matter in spite of active attempts to retain bowel contents
  3. fecal seepage: leakage of stool following otherwise normal evacuation

Epidemiology
- the incidence of fecal incontinence differs by setting: community (17-36%), hospital (16%) and nursing home (33-65%)
- risk factors: constipation, age >80 yr, female sex, urinary incontinence, impaired mobility, dementia, neurologic disease

Etiology
- physiological changes with age >80 yr (e.g. decreased external sphincter strength, decreased resting tone of internal sphincter, weakened anal squeeze, increased rectal compliance, and impaired anal sensation)
- trauma (e.g. vaginal delivery, pudendal nerve damage, cauda equina)
- iatrogenic
  - surgical (e.g. anorectal surgery, lateral internal sphincterotomy, hemorrhoidectomy, colorectal resection)
  - radiation (e.g. pelvic radiation)
- neurogenic (e.g. neuropathy, stroke, MS, diabetic neuropathy)
- anorectal/colorectal diseases (e.g. rectal prolapse, hemorrhoids, IBD, rectocele, cancer)
- medication (e.g. laxative, anticholinergics, antidepressants, caffeine, muscle relaxants)
- cognitive (e.g. dementia, willful soiling with psychosis)
- constipation/fecal impaction

Investigations (if cause not apparent from history and physical)
- differentiate true incontinence from frequency and urgency (e.g. IBS, IBD)
- stool studies
- endorectal ultrasound
- colonoscopy, sigmoidoscopy, anoscopy
- anorectal manometry/functional testing

Figure 2. Treatment algorithm for the management of chronic constipation in the elderly
Adapted from: Clin Interv Aging 2010;5:163-171

Chronic Constipation

Fecal Impaction

NO

Remove constipating medications (if possible)
Increase fluid intake
Increase activity or exercise
Increase fibre intake (20-30 g/d)
Start timed toilet training

NO

Milk of magnesia
Lactulose
Peg-Lyte
Senna compounds
Bisacodyl

Perform manual disimpaction
Use enemas and/or suppositories
Start bowel regimen to prevent recurrence

Effective

NO

Polyethylene glycol (PEG3350 high dose)

Effective

NO

Lubiprostone
Biofeedback therapy (dyssynergic defecation)
Alvimopan
Methylnaltrexone (opioid-induced constipation)

NO

YES

YES

NO
Management
- physiological changes with age: medication management (anti-motility agents (e.g. loperamide), diet/bulking agents for loose stool) increase fluid intake, biofeedback, retraining of pelvic floor muscles, surgery
- trauma: direct surgical repair or augmentation of the sphincters
- iatrogenic: surgical repair, artificial sphincters
- neurogenic: medication management, abdominal massage, digital stimulation for dysfunction, biofeedback and behavioural training, prevent autonomic dysreflexia in spinal injury
- anorectal/colorectal diseases: treat underlying cause (optimize IBD medications), surgical (e.g. mass removal, prolapse repair, hemorrhoid removal, colostomy)
- medication-related causes: stop laxatives, lower dose or discontinue any other offending agents
- cognitive: regular defecation program in patients with dementia, psychiatric consult (optimize medications and cognitive function)
- constipation/fecal impaction: disimpaction, prevent impaction, enema or rectal irrigation

URINARY INCONTINENCE
- see Urology, U6

Definition
- complaint of any involuntary loss of urine
- there are 4 subtypes:
  1. stress incontinence: leakage associated with physical strain
  2. urge incontinence: leakage associated with strong urge to urinate
  3. overflow incontinence: leakage associated with poor bladder emptying
  4. functional incontinence: leakage due to illness or disability not related to the urinary tract

Epidemiology
- 15-30% prevalence dwelling in community and at least 50% of institutionalized seniors
- morbidity: cellulitis, pressure ulcers, urinary tract infections, falls with fractures, sleep deprivation, social withdrawal, depression, sexual dysfunction
- not associated with increased mortality
- risk factors: impaired mobility, falls, medications, depression, TIA/stroke, dementia, CHF, obesity

Etiology
- physiologic changes with age: decreased bladder capacity
- genitourinary diseases (e.g. cystitis, urethritis, benign prostatic hyperplasia)
- neurogenic (e.g. cauda equina syndrome, stroke, MS)
- iatrogenic: prostate surgery
- trauma: pelvic trauma, traumatic spinal cord injury
- drugs (e.g. alcohol, loop diuretics, sedative hypnotics, GABAergic agents)
- cognitive (e.g. dementia, depression)
- functional impairment (e.g. arthritis, poor vision)

Investigations
- urinalysis and culture

Management
- lifestyle modification: avoid excessive fluid intake and alcohol
- pharmacologic: β-adrenergic agonists to reduce involuntary bladder contractions
- physiologic changes with age: pelvic muscle exercises, bladder training, biofeedback
- genitourinary diseases: treat underlying cause (empiric antimicrobial treatment for cystitis, α blockers/5-α reductase inhibitors for benign prostatic hyperplasia)
- functional impairment: incontinence pads, environmental modification, personal assistance
- cognitive: referral to incontinence program if needed

Immobility

Complications
- cardiovascular: orthostatic hypotension, venous thrombosis, embolism
- respiratory: decreased ventilation, atelectasis, pneumonia
- gastrointestinal: anorexia, constipation, incontinence, dehydration, malnutrition
- genitourinary: infection, urinary retention, bladder calculi, incontinence
- musculoskeletal: atrophy, contractures, bone loss
- skin: pressure ulcers
- psychological: sensory deprivation, delirium, depression
Pressure Ulcers

- see Plastic Surgery, PL17

Definition
- any lesion caused by unrelieved pressure resulting in damage of underlying tissue; usually develops over bony prominences

Risk Factors
- extrinsic: friction, pressure, shear force
- intrinsic: immobility, malnutrition, moisture, sensory loss
- geriatric: age related skin changes, bed-bound, cognitive impairment, chronic illness, use of anti-hypertensive medications

Table 4. Classification of Pressure Ulcers

<table>
<thead>
<tr>
<th>Stage</th>
<th>Changes include skin temperature, tissue consistency or sensation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stage I</td>
<td>An area of persistent erythema in lightly pigmented, intact skin; in darker skin, it may appear red, blue or purple</td>
</tr>
<tr>
<td>Stage II</td>
<td>Partial thickness skin loss involving the epidermis, dermis or both</td>
</tr>
<tr>
<td>Stage III</td>
<td>The ulcer is superficial and presents as an abrasion, blister or shallow crater</td>
</tr>
<tr>
<td>Stage IV</td>
<td>Full thickness skin loss involving damage or necrosis of subcutaneous tissue which may extend down to, but not through, underlying fascia</td>
</tr>
<tr>
<td></td>
<td>Presents as a deep crater with or without undermining of adjacent tissue</td>
</tr>
<tr>
<td></td>
<td>May have associated undermining and/or sinus tracts</td>
</tr>
</tbody>
</table>

Prevention
- pressure reduction
- frequent repositioning
- use validated pressure injury risk assessment tools on admission for those identified to be at risk for skin breakdown (Canadian Association of Wound Care, 2018)

Treatment
- optimize nutritional status
- minimize pressure on wound
- analgesia
- all ulcers with necrosis warrant debridement (mechanical, enzymatic and autolytic are non-urgent forms of debridement, whereas sharp debridement is performed urgently due to risk for sepsis or cellulitis)
- dressing application (exudate absorbing, barrier products to reduce friction)
- maintain moist wound environment to enable re-epithelialization
- treatment of wound infections (topical gentamicin, silver sulfadiazine, mupirocin)
- diabetic foot ulcers: offloading with removable cast walker (e.g. aircast boot), orthopedic shoes and orthotics
- swab wounds not demonstrating clinical improvement for C&S; biopsy chronic wounds to rule out malignancy
- referral to Wound Care
- consider other treatment options
  - negative pressure wound therapy/vacuum-assisted closure
  - biological agents: application of fibroblast growth factor, platelet-derived growth factor to wound
  - non-contact normothermic wound therapy
  - electrotherapy
### Hazards of Hospitalization

### Elder Abuse

**Definition**
- includes physical abuse, sexual abuse, emotional/psychological abuse, financial exploitation and neglect
- elder abuse is a criminal offence under the Criminal Code of Canada and in most U.S. states

**Epidemiology**
- in Canada in 2013, almost 3000 seniors were victims of family violence. The perpetrators of family violence against seniors were identified to be their grown child (43% of cases) and their spouses (28% of the cases)
- in older adults aged ≥60 yr, elder abuse is estimated to occur in 10% of patients
- insufficient evidence to include/exclude screening in the Periodic Health Exam

**Risk Factors**

Table 6. Risk Factors for Elder Abuse

<table>
<thead>
<tr>
<th>Situational Factors</th>
<th>Social</th>
</tr>
</thead>
<tbody>
<tr>
<td>Victim Characteristics</td>
<td>Physical or emotional dependence on caregiver</td>

</tr>
<tr>
<td></td>
<td>Dependency on older adult (e.g. financial dependency)</td>
</tr>
</tbody>
</table>

### Presbycusis

- see Otolaryngology, OT19
Driving Competency

Reporting Requirements

- physician-reporting to the Ministry of Transportation is mandatory in all provinces and territories except in Quebec, Nova Scotia, and Alberta, where it is discretionary
- British Columbia, Ontario: must refer for re-test at ≥80 yr
- not an issue unique to geriatrics – any patient may suffer from a medical condition that impairs their ability to drive and should be reported
- in the U.S., varies by state

Conditions that may Impair Driving

<table>
<thead>
<tr>
<th>Table 7. Conditions that Impair Driving</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Alcohol</strong></td>
</tr>
<tr>
<td>Patients with history of impaired driving and those with a high probability of future impaired driving should not drive until further assessed</td>
</tr>
<tr>
<td>Alcohol dependence or abuse: if suspected, should be advised not to drive</td>
</tr>
<tr>
<td>Alcohol withdrawal seizure: must complete a rehabilitation program and remain abstinent and seizure-free for 6 mo before driving</td>
</tr>
<tr>
<td><strong>Blood Pressure Abnormalities</strong></td>
</tr>
<tr>
<td>Hypertension: sustained BP &gt;170/110 should be evaluated carefully</td>
</tr>
<tr>
<td>Hypotension: sustained BP &lt;90/60; if syncopeal, discontinue driving until syncope is treated and preventable</td>
</tr>
<tr>
<td><strong>Cardiovascular Disease</strong></td>
</tr>
<tr>
<td>Suspected asymptomatic CAD or stable angina: no restrictions</td>
</tr>
<tr>
<td>STEMI, NSTEMI with significant LV damage, coronary artery bypass surgery: no driving for 1 mo following hospital discharge</td>
</tr>
<tr>
<td>NSTEMI with minor LV damage, unstable angina: no driving for 48 h if PCI or 7 d if no PCI performed</td>
</tr>
<tr>
<td><strong>Cerebrovascular Conditions</strong></td>
</tr>
<tr>
<td>TIA: should not be allowed to drive until a medical assessment is completed</td>
</tr>
<tr>
<td>Stroke: should not drive for at least 1 mo; may resume driving if functionally able; no clinically significant motor, cognitive, perceptual or vision deficits; no obvious risk of sudden recurrence; underlying cause appropriately treated; no post-stroke seizure</td>
</tr>
<tr>
<td><strong>COPD</strong></td>
</tr>
<tr>
<td>Mild/moderate impairment: no restrictions</td>
</tr>
<tr>
<td>Moderate or severe impairment requiring supplemental oxygen: road test with supplemental oxygen</td>
</tr>
<tr>
<td><strong>Cognitive Impairment/ Dementia</strong></td>
</tr>
<tr>
<td>Moderate to severe dementia is a contraindication to driving; defined as the “inability to independently perform 2 or more IADLs or any basic ADL”</td>
</tr>
<tr>
<td>Patients with mild dementia should be assessed; if indicated, refer to specialized driving testing centre; if deemed fit to drive, re-evaluate patient every 6-12 mo</td>
</tr>
<tr>
<td>Poor performance on MMSE, clock drawing or Trails B suggests a need to investigate driving ability further</td>
</tr>
<tr>
<td>MMSE score alone (whether normal or low) is insufficient to determine fitness to drive</td>
</tr>
<tr>
<td><strong>Diabetes</strong></td>
</tr>
<tr>
<td>Diet controlled or oral hypoglycemic agents: no restrictions in absence of diabetes complications that may impair ability to drive (e.g. retinopathy, nephropathy, neuropathy, cardiovascular or cerebrovascular disease)</td>
</tr>
<tr>
<td>Insulin use: may drive if no complications (as above) and no severe hypoglycemic episode in the last 6 mo</td>
</tr>
<tr>
<td><strong>Drugs</strong></td>
</tr>
<tr>
<td>Be aware of: analgesics, anticholinergics, anticonvulsants, antidepressants, antipsychotics, opiates, sedatives, stimulants</td>
</tr>
<tr>
<td>Degree of impairment varies: patients should be warned of the medication/withdrawal effect on driving</td>
</tr>
<tr>
<td><strong>Hearing Loss</strong></td>
</tr>
<tr>
<td>Effect of impaired hearing on ability to drive safely is controversial</td>
</tr>
<tr>
<td>Acute labyrinthitis, positional vertigo with horizontal head movement, recurrent vertigo: advise not to drive until condition resolves</td>
</tr>
<tr>
<td><strong>Musculoskeletal Disorders</strong></td>
</tr>
<tr>
<td>Physician’s role is to report etiology, prognosis and extent of disability (pain, range of motion, coordination, muscle strength)</td>
</tr>
<tr>
<td><strong>Post-Operative</strong></td>
</tr>
<tr>
<td>Outpatient, conscious sedation: no driving for 24 h</td>
</tr>
<tr>
<td>Outpatient, general anesthesia: no driving for &gt;24 h</td>
</tr>
<tr>
<td><strong>Seizures</strong></td>
</tr>
<tr>
<td>First, single, unprovoked: no driving for 3 mo until complete neurologic assessment, EEG, CT head</td>
</tr>
<tr>
<td>Epilepsy: can drive if seizure-free on medication and physician has insight into patient compliance</td>
</tr>
<tr>
<td><strong>Sleep Disorders</strong></td>
</tr>
<tr>
<td>If patient is believed to be at risk due to a symptomatic sleep disorder but refuses investigation with a sleep study or refuses appropriate treatment, the patient should not drive</td>
</tr>
<tr>
<td><strong>Visual Impairment</strong></td>
</tr>
<tr>
<td>Visual acuity: contraindicated to drive if &lt;20/50 with both eyes examined simultaneously</td>
</tr>
<tr>
<td>Visual field: contraindicated to drive if &lt;120° along horizontal meridian and 15° continuous above and below fixation with both eyes examined simultaneously</td>
</tr>
</tbody>
</table>

N.B. guidelines included refer specifically to private driving; please see CMA guidelines for commercial driving
**Health Care Institutions**

Table 8. Classification of Health Care Services and Institutions

<table>
<thead>
<tr>
<th>Institution/Service</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Community Support Services</td>
<td>Health care services offered at home for those who can live independently at home or under the care of family members including professional health care services, personal care and support (ADL assistance), homemaking (IADL assistance), community support services (e.g. transportation, meal delivery, day programs, caregiver relief, security checks, etc.)</td>
</tr>
<tr>
<td>Rehabilitation</td>
<td>Health care services offered in an institution to optimize patients’ function, independence and quality of life</td>
</tr>
<tr>
<td>Residential</td>
<td>Divided into short (&lt;60-90 d/yr) and long (indefinite) stay</td>
</tr>
<tr>
<td>a) Seniors Affordable Housing</td>
<td>Seniors who live independently and manage their own care, but prefer to live near other seniors; usually has accessibility features; rent is adjusted based on income</td>
</tr>
<tr>
<td>b) Retirement Home</td>
<td>Residents are fairly independent and require minimal support with ADLs and IADLs; often privately owned</td>
</tr>
<tr>
<td>c) Supportive Housing</td>
<td>Residents require minimal to moderate assistance with daily activities while living independently; often rental units in an apartment; may offer physiotherapy and rehabilitation services</td>
</tr>
<tr>
<td>d) Long-term Care/Skilled Nursing Facility</td>
<td>Around the clock nursing care and on-call physician coverage; often offers occupational therapy, physiotherapy, respiratory therapy, and rehabilitation services; may be used short-term for caregiver respite or for supportive patient care to regain strength and confidence after leaving the hospital</td>
</tr>
<tr>
<td>e) Hospice</td>
<td>Free-standing facility or designated floor in a hospital or nursing home for care of terminally ill patients and their families; focus is on quality of life and often requires prognosis ≤3 mo</td>
</tr>
</tbody>
</table>

- names of community health care institutions, types of facilities, and services offered vary between geographical locations
- factors to consider when seeking services/institutions: level of care required, support networks, duration of stay, cost

**Geriatric Pharmacology**

**Pharmacokinetics**

Table 9. Age-Associated Pharmacokinetics

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Age Effect</th>
<th>Implications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Absorption</td>
<td>Increased gastric pH, delayed gastric emptying</td>
<td>Drug-food and drug-drug interactions are more likely to affect absorption</td>
</tr>
<tr>
<td>Distribution</td>
<td>Increased total body fat, decreased lean body mass and total body water</td>
<td>Lipophilic drugs have a larger volume of distribution, decreased volume of distribution of hydrophilic drugs</td>
</tr>
<tr>
<td>Metabolism (less significant)</td>
<td>Decreased hepatic mass and hepatic blood flow, impaired phase I reactions (oxidative system)</td>
<td>Lower doses may be therapeutic</td>
</tr>
<tr>
<td>Elimination</td>
<td>Decreased renal blood flow, glomerular filtration rate, tubular secretion</td>
<td>Lower doses may be therapeutic</td>
</tr>
</tbody>
</table>

**Pharmacodynamics**

**Drug Sensitivity**
- changes in pharmacokinetics as well as intrinsic sensitivity lead to altered drug responses
- increased sensitivity to warfarin, sedatives, antipsychotics, anticholinergics, digoxin, and narcotics
- decreased sensitivity to β-blockers and β-adrenergic stimulants, though may have increased sensitivity

**Decreased Homeostasis**
- poorer compensatory mechanisms leading to more adverse reactions (e.g. bleeding with NSAIDs/anticoagulants, altered mental status with anticholinergic/sympathomimetic/anti-Parkinsonian drugs)
**Polypharmacy**

**Definition**
- prescription, administration or use of more medications than are clinically indicated

**Epidemiology**
- in Canada, >60% of elderly individuals reported using ≥5 medications
- hospitalized elderly are given an average of 10 medications during admission

**Risk Factors for Non-Compliance**
- greater number of medications (compliance with 1 medication is 80%, but drops to 25% with ≥6 medications)
- increased dosing frequency, complicated container design, financial constraints, and cognitive impairment

**Adverse Drug Reactions (ADRs)**
- any noxious or unintended response to a drug that occurs at doses used for prophylaxis or therapy
- risk factors in the elderly
  - intrinsic: comorbidities (>5), age >85, low BMI, age-related changes in pharmacokinetics and pharmacodynamics, CrCl <50 mL/min
  - extrinsic: number of medications, (>9 medications, >12 doses/d), multiple prescribers, unreliable drug history, prior ADR
- prescribing cascade: process whereby an ADR is misinterpreted as a new medical condition, and a subsequent drug is prescribed to treat the initial drug-induced event. Providers should ask themselves:
  - is the new drug being prescribed to address an adverse event from a previously prescribed drug therapy?
  - is the initial drug therapy potentially leading to a prescribing cascade really needed?
  - what are the harms and benefits of continuing the initial drug therapy?

**Preventing Polypharmacy**
- consider drug: safer side effect profiles, convenient dosing schedules, convenient route, efficacy
- consider patient: other medications, clinical indications, medical comorbidities
- review drug list regularly to eliminate medications with no clinical indication or with evidence of toxicity
- avoid treating an ADR with another medication

**Inappropriate Prescribing in the Elderly**

**Epidemiology**
- the estimated prevalence of potentially inappropriate prescribing ranges from 12-40%

**Beers Criteria**
- a list of medications to avoid in adults ≥65 yr due to safety concerns
- 2015 update lists drugs that should be avoided or dose-adjusted based on kidney function, as well as drug-drug interactions associated with harms in older adults
- examples include long-acting benzodiazepines, strong anticholinergics, high-dose sedatives
- the elderly are often under-treated (ACEI, ASA, β-blockers, thrombolytics, oral anticoagulants)

**STOPP/START Criteria**
- another screening tool for potentially inappropriate prescribing in the elderly
  - STOPP: Screening Tool of Older Person's Prescriptions
    - systems-based list of medications contraindicated in adults ≥65 in the context of their diagnoses
  - START: Screening Tool to Alert doctors to Right Treatment
    - systems-based list of medications indicated in adults ≥65 in the context of their diagnoses

<tbody>
<tr>
<td>Delirium in Older Persons: Advances in Diagnosis and Treatment</td>
<td>JAMA 2017; 318(12):1161-1174</td>
<td>Advances in diagnosis can improve recognition and risk stratification of delirium. Prevention of delirium using nonpharmacologic approaches is effective, while pharmacologic prevention and treatment of delirium remains controversial.</td>
</tr>
<tr>
<td>Assessment and management of falls in older people</td>
<td>Can Med Assoc J 2014;186(16):E610-21</td>
<td>Targeted history and physical examination, covering potential home hazards, cognitive and visual impairment, functional limitations, medications, orthostatic hypotension, and gait and balance abnormalities, can be used to identify risk factors for falls. Numerous interventions (single and multicomponent) can decrease the risk of falls. At a minimum, patients who have experienced a fall should be encouraged to participate in an approved exercise program to help prevent further falls.</td>
</tr>
<tr>
<td>Dementia prevention, intervention, and care</td>
<td>Lancet 2017; 390(10113): 2673-2734</td>
<td>Recommend active treatment of hypertension in middle aged (45–65 yr) and older people (aged older than 65 yr) without dementia to reduce dementia incidence. Interventions for other risk factors including more childhood education, exercise, maintaining social engagement, reducing smoking, and management of hearing loss, depression, diabetes, and obesity could delay or prevent a third of dementia cases.</td>
</tr>
<tr>
<td>Optimal management of urinary tract infections in older people</td>
<td>Clin Interv Aging 2011;8:173-180</td>
<td>UTIs are over diagnosed and over treated in older people. Asymptomatic bacteriuria is very common in later life and should not be screened for or treated.</td>
</tr>
<tr>
<td>Delirium is a strong risk factor for dementia in the oldest-old: a population-based cohort study</td>
<td>Brain 2012;135(9): 2809-16</td>
<td>First population study to show that delirium is a strong risk factor for dementia and cognitive decline in elderly patients.</td>
</tr>
<tr>
<td>Donepezil and Memantine for Moderate-to-Severe Alzheimer’s Disease</td>
<td>New Engl J Med 2012;366:892-903</td>
<td>Continued treatment with donepezil was associated with cognitive benefits over the course of 12 mo in patients with moderate or severe Alzheimer’s disease.</td>
</tr>
<tr>
<td>Hip protectors for fracture prevention</td>

### Basic Anatomy Review

#### A. EXTERNAL GENITALIA
- blood supply: internal pudendal artery
- sensory innervation: pudendal nerve
- lymphatic drainage: inguinal nodes

#### B. VAGINA
- muscular canal extending from cervix to vulva, anterior to rectum and posterior to bladder
- lined by rugated, stratified squamous epithelium
- upper vagina separated by cervix into anterior, posterior, and lateral fornices
- blood supply: vaginal branch of internal pudendal artery with anastomoses from uterine, inferior vesical, and middle rectal arteries

#### C. UTERUS
- thick walled, muscular organ between bladder and rectum, consisting of two major parts:
- uterus corpus
  - blood supply: uterine artery (branch of the internal iliac artery, anterior division)
  - cervix
    - blood supply: cervical branch of uterine artery
- supported by the pelvic diaphragm, the pelvic organs, and 4 paired sets of ligaments
  - round ligaments: travel from anterior surface of uterus, through broad ligaments, and inguinal canals then terminate in the labia majora
    - function: anteversion
  - blood supply: Samson's artery (branch of uterine artery running through round ligament)
- uterosacral ligaments: arise from sacral fascia and insert into posterior inferior uterus
  - function: mechanical support for uterus, prevent prolapse and contain autonomic nerve fibres
- cardinal ligaments: extend from lateral pelvic walls and insert into lateral cervix and vagina
  - function: mechanical support, prevent prolapse
- broad ligaments: pass from lateral pelvic wall to sides of uterus; contain fallopian tube, round ligament, ovarian ligament, nerves, vessels, and lymphatics

---

**Figure 1. Vulva and perineum**

- Prepuce

- Ischiocavernosus muscle
- Bulbospongious muscle
- Superficial transverse perineal muscle
- Levator ani muscle
- External anal sphincter
- Anus

© Marina Chang 2013
• infundibulopelvic ligament (suspensory ligament of the ovary): continuous tissue that connects ovary to pelvic wall
  • contains the ovarian artery, ovarian vein, ovarian plexus, and lymphatic vessels
  • position of the uterus
    • anteverted (majority), retroverted, neutral

---

**Figure 2. Genital organs and positioning of the uterus**

**D. FALLOPIAN TUBES**
- 8-14 cm muscular tubes extending laterally from the uterus to the ovary
- interstitial, isthmic, ampullary, and infundibuliform segments; terminates at fimbriae
- mesosalpinx: peritoneal fold that attaches fallopian tube to broad ligament
- blood supply: uterine and ovarian arteries

**E. OVARIES**
- consist of cortex with ova and medulla with blood supply
- supported by infundibulopelvic ligament (suspensory ligament of ovary)
- mesovarium: peritoneal fold that attaches ovary to broad ligament
- blood supply: ovarian arteries (branches off of aorta), left ovarian vein (drains into left renal vein), right ovarian vein (drains into inferior vena cava)

---

**Figure 3. Vascular supply**

**Determination of Uterine Position by Clinical Exam**
- If cervix faces anteriorly (under the urethra and less easily accessible), i.e. toward vaginal orifice, more likely RETROVERTED UTERUS
- If cervix faces posteriorly (easily accessible), i.e. toward sacrum or rectum, more likely ANTEVERTED UTERUS
- If uterus palpable on bimanual exam, more likely ANTEVERTED UTERUS

**“Water Under the Bridge”**
The ureters run posterior to the uterine arteries

**Common Anatomy Questions in the OR**
- What is the origin of the left and right ovarian arteries?
  Descending aorta
- What are the drainage sites for the left and right ovarian veins?
  Left to left renal vein, right to inferior vena cava
- What is the most common place to locate the ureter?
  Pelvic brim, medial leaf of the broad ligament as it passes under the uterine artery
- Which artery runs under the round ligament?
  Sampson’s artery
Menstruation

</tbody>
</table>

Characteristics:

- Menarche: 10-15 yr
- Average: 12.2 yr
- Entire cycle: 26 ± 7 d with bleeding for 1-6 d
- 25-80 mL blood loss per cycle

**ESTROGEN**

ESTROGEN is the main hormone in the follicular/proliferative phase and is stimulated by FSH. As the level increases it acts negatively on FSH. The majority of estrogen is secreted by the dominant follicle.

Estrogen effects:
- On the follicles in the ovaries
- Reduces atresia
- On the endometrium
- Proliferation of glandular and stromal tissue
- On all target tissues
- Decreases E receptors

**PROGESTERONE**

PROGESTERONE is the main hormone in the luteal/secretory phase and is stimulated by LH. Increased progesterone acts negatively on LH and is secreted by the corpus luteum (remnant of dominant follicle).

Progesterone effects:
- On the endometrium
  - Cessation of mitoses (stops building endometrium up)
  - "Organization" of glands (initiates secretions from glands)
  - Inhibits macrophages, interleukin-8, and enzymes from degrading endometrium
- On all target tissues
  - Decrease E receptors (the "anti-estrogen" effect)
  - Decrease P receptors
Menstruation

Stages of Puberty

- see Pediatrics, P31
- adrenarche: increased secretion of adrenal androgens; usually precedes gonadarche by 2 yr
- gonadarche: increased secretion of gonadal sex steroids; ~age 8 yr
- thelarche: breast development
- pubarche: pubic and axillary hair development
- menarche: onset of menses, usually following peak height velocity and/or 2 yr following breast budding

Premenstrual Syndrome

- synonyms: “ovarian cycle syndrome,” “menstrual molimina” (moodiness)

Etiology

- multifactorial: not completely understood; genetics likely play a role
- CNS-mediated neurotransmitter (serotonin, dopamine, GABA) interactions with sex steroids (P, E, and T)
- serotonergic dysregulation – currently most plausible theory

Diagnostic Criteria for Premenstrual Syndrome

- at least one affective and one somatic symptom during the 5 d before menses in each of the three prior menstrual cycles
  - affective: depression, angry outbursts, irritability, anxiety, confusion, social withdrawal
  - somatic: breast tenderness or swelling, abdominal bloating, headache, swelling of extremities, joint or muscle pain, or weight gain
- symptoms relieved within 4 d of onset of menses and do not recur until at least day 13 of cycle
- symptoms present in the absence of any pharmacologic therapy, hormone ingestion, drug or alcohol use
- symptoms occur reproducibly during 2 cycles of prospective recording
- patient suffers from identifiable dysfunction in social or occupational performance

Premenstrual Dysphoric Disorder

Clinical Feature

- irritability, depressed mood
- breast pain and bloating

Diagnostic Criteria for Premenstrual Dysphoric Disorder

- at least 5 of the following 11 symptoms during most menstrual cycles of the last year (with at least 1 of the first 4)
  - depressed mood or hopelessness
  - anxiety or tension
  - affective instability
  - anger or irritability
  - decreased interest in activities
  - difficulty concentrating
  - lethargy
  - change in appetite
  - hypersomnia or insomnia
  - feeling overwhelmed
  - physical symptoms: breast tenderness/swelling, headaches, joint/muscle pain, bloating, or weight gain
- symptoms cause significant distress and/or interfere with social or occupational functioning
- symptoms must be present during the week prior to menses and resolve within a few days after onset of menses
- may be superimposed on other psychiatric disorders, provided it is not merely an exacerbation of another disorder

Figure 5. RCOG guidelines for treatment of premenstrual syndrome
Adapted from source: https://www.rcog.org.uk/globalassets/documents/guidelines/gt48managementpremenstrualsyndrome.pdf

Premenstrual Syndrome Treatment

First Line
- Exercise, cognitive behavioural therapy, vitamin B6
- "combined hormonal contraception
- Continuous or luteal phase (day 15-28) low dose SSRIs (e.g. citalopram/escitalopram 10 mg)

Second Line
- Estradiol patches (100 micrograms) + micronised progesterone (100 mg or 200 mg (day 17-28), orally or vaginally) or LNG-IUS 52 mg
- Higher dose SSRIs continuously or luteal phase (e.g. citalopram/escitalopram 20-40 mg)

Third Line
- GnRH analogues + add-back HRT

Fourth Line
- Surgical treatment ± HRT

Tanner Stage

Thelarche
1. None
2. Breast bud
3. Further enlargement of areolae and breasts with no separation of contours
4. 2º mound of areolae and papilla
5. Areolae recessed to general contour of breast – adult

Pubarche
1. None
2. Downy hair along labia only
3. Darker/coarse hair extends over pubis
4. Adult-type hair with no thigh involvement
5. Adult hair in distribution and type; extends over thighs. Not all patients achieve Tanner Stage 5. For image see Pediatrics, P32

Premenstrual Syndrome

Physiological and emotional disturbances that occur 1-2 wk prior to menses and last until a few days after onset of menses; common symptoms include depression, irritability, tearfulness, and mood swings

Stages of Puberty

"Boobs, Pubes, Grow, Flow"
Thelarche, Pubarche, Growth spurt, Menarche

Figure 5. RCOG guidelines for treatment of premenstrual syndrome
Adapted from source: https://www.rcog.org.uk/globalassets/documents/guidelines/gt48managementpremenstrualsyndrome.pdf

Premenstrual Dysphoric Disorder

Clinical Feature

- irritability, depressed mood
- breast pain and bloating

Diagnostic Criteria for Premenstrual Dysphoric Disorder

- at least 5 of the following 11 symptoms during most menstrual cycles of the last year (with at least 1 of the first 4)
  - depressed mood or hopelessness
  - anxiety or tension
  - affective instability
  - anger or irritability
  - decreased interest in activities
  - difficulty concentrating
  - lethargy
  - change in appetite
  - hypersomnia or insomnia
  - feeling overwhelmed
  - physical symptoms: breast tenderness/swelling, headaches, joint/muscle pain, bloating, or weight gain
- symptoms cause significant distress and/or interfere with social or occupational functioning
- symptoms must be present during the week prior to menses and resolve within a few days after onset of menses
- may be superimposed on other psychiatric disorders, provided it is not merely an exacerbation of another disorder
Common Investigations and Procedures

Imaging

Ultrasound (U/S)
- transabdominal or transvaginal U/S is the imaging modality of choice for pelvic structures
- transvaginal U/S provides better resolution of uterus and adnexal structures
  - detects early pregnancy if β-hCG ≥1500 (β-hCG must be ≥6500 for transabdominal U/S)
  - may be used to identify pelvic pathology
  - identify ectopic pregnancy, intrauterine pregnancy
  - assess uterine, adnexal, cul-de-sac, and ovarian masses (e.g., solid or cystic)
  - determine endometrial thickness, locate/characterize fibroids
  - monitor follicles during assisted reproduction
  - assess endometrial lining in postmenopausal women

Endometrial Biopsy

- performed in the office using an endometrial suction curette (pipelle) guided through the cervix to aspirate fragments of endometrium
  - pre-treatment with misoprostol (Cytotec*) is optional
- more invasive procedure (i.e., D&C) may be done in the office or operating room ± hysteroscopy. This may be required if endometrial biopsy is not possible in the office setting or if there is suspicion for an endometrial polyp
- indications
  - AUB/PMB
    - age >40
    - risk factors for or history of endometrial cancer
    - failure of medical treatment
    - significant intermenstrual bleeding
    - consider in women with infrequent menses suggesting anovulatory cycles

Hysterectomy

Indications
- uterine fibroids
- endometriosis, adenomyosis
- uterine prolapse
- pelvic pain
- AUB
- cancer (endometrium, ovaries, fallopian tubes, cervix)

Complications
- general anesthetic
- bleeding
- infection
- injury to other organs (ureter, bladder, rectum)
- loss of ovarian function (if ovaries removed, iatrogenic menopause)

Approaches
1. Open (abdominal approach): uterus removed via transverse (Pfannenstiel) or midline laparotomy
2. Minimally invasive approaches
   - vaginal hysterectomy: entire procedure performed through the vagina. No abdominal incisions
   - laparoscopic-assisted vaginal hysterectomy: vascular pedicles are divided by a combination of laparoscopic and vaginal approaches
   - total laparoscopic hysterectomy: all vascular pedicles including the colpotomy approached laparoscopically and removed through the vagina
   - robotic: a type of laparoscopic approach. May be advantageous in high BMI patients. More costly

Women should be counselled about the benefits and risks of removing the ovaries, the risk of ovarian cancer versus the long-term health implications of earlier menopause.
Table 1. Classification of Hysterectomy

</tr>
</tbody>
</table>
Investigations

Figure 6. Diagnostic approach to amenorrhea

- β-hCG, hormonal workup (TSH, prolactin, FSH, LH, androgens, estradiol)
- progesterone challenge to assess estrogen status
  - medroxyprogesterone acetate (Provera®) 10 mg PO OD for 10-14 d
  - any uterine bleed within 2-7 d after completion of Provera® is considered to be a positive test/
    withdrawal bleed
  - withdrawal bleed suggests presence of adequate estrogen to thicken the endometrium; thus
    withdrawal of progesterone results in bleeding
  - if no bleeding occurs, this may be secondary to inadequate estrogen (hypoestrogenism),
    excessive androgens, or progesterones (decidualization) or pregnancy
- karyotype: indicated if primary ovarian insufficiency or absent puberty
- U/S to confirm normal anatomy, identify PCOS

### Abnormal Uterine Bleeding

**Figure 7. Diagnostic approach to abnormal uterine bleeding**

**Approach**
- menstrual bleeding should be evaluated by ascertaining: frequency/regularity of menses, duration, volume of flow, impact on quality of life, and timing (inter or premenstrual or breakthrough)
- is it regular?
  - regular: cycle to cycle variability of <20 d – “Can you predict your menses within 20 days?”
  - irregular: cycle to cycle variability of ≥20 d
- is it heavy?
  - ≥80 cc of blood loss per cycle or
  - ≥8 d of bleeding per cycle or
  - bleeding that significantly affects quality of life
- is it structural?
  - PALM
- is it non-structural?
  - COEIN

Postmenopausal bleeding is endometrial cancer until proven otherwise

Abnormal Uterine Bleeding Change in frequency, duration, or amount of menstrual flow that affects quality of life

</tr>
<tr>
<td>Not yet classified (AUB-N)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Treatment**

- resuscitate patient if hemodynamically unstable
- treat underlying disorders
  - if anatomic lesions and systemic disease have been ruled out, consider AUB
- medical
  - mild AUB
    - NSAIDs
    - anti-fibrinolytic (e.g. Cyklokapron®) at time of menses
    - combined hormonal contraceptive
    - progestins (Provera®) on first 10-14 d of each month or every 3 mo if AUB-O
    - Mirena® IUD
    - correct anemia - iron
  - acute, severe AUB
    - replace fluid losses, consider admission
      a) estrogen (Premarin®) 25 mg IV q4h x 24 h with Gravol® 50 mg IV/PO q4h or anti-fibrinolytic (e.g. Cyklokapron®) 10 mg/kg IV q8h (rarely used)
      b) tapering OCP regimen, 35 µg pill tid x7d then taper to 1 pill/d for 3wk with Gravol® 50 mg IV/PO q4h
    - or taper to 1 tab tid x 2 d → bid x 2 d → OD (more commonly used)
  - after (a) or (b), maintain patient on monophasic OCP for next several months or consider alternative medical treatment
    - medical (can also consider):
      - high dose progestins
      - danazol (Danocrine®)
      - GnRH agonists (e.g. Lupron®) with add-back if taken for >6 mo
      - ulipristal acetate
  - surgical
    - endometrial ablation
      - if finished childbearing
      - repeat procedure may be required if symptom recur, especially if <40 yr
  - hysterectomy: definitive treatment
Dysmenorrhea

Etiology
- primary/idiopathic
- secondary (acquired)
  - endometriosis
  - adenomyosis
  - uterine polyps
  - uterine anomalies (e.g., non-communicating uterine horn)
  - leiomyoma
  - intrauterine synechiae
  - ovarian cysts
  - cervical stenosis
  - imperforate hymen, transverse vaginal septum
  - pelvic inflammatory disease
  - IUD (copper)
  - foreign body

Table 6. Comparison of Primary and Secondary Dysmenorrhea

<th>Secondary Dysmenorrhea</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Features</strong></td>
<td>Recurrent, crampy lower abdominal pain that occurs during menses in the absence of demonstrable disease</td>
<td>Similar features as primary dysmenorrhea but with an underlying disorder that can account for the symptoms, such as endometriosis, adenomyosis or uterine fibroids</td>
</tr>
<tr>
<td><strong>Signs and Symptoms</strong></td>
<td>Colicky pain in abdomen, radiating to the lower back, labia, and inner thighs beginning hours before onset of bleeding and persisting for hours or days (48-72 h) Associated symptoms: N/V, altered bowel habits, headaches, fatigue (prostaglandin-associated)</td>
<td>Associated dyspareunia, abnormal bleeding, infertility</td>
</tr>
<tr>
<td><strong>Diagnosis</strong></td>
<td>Assess for associated dyspareunia, abnormal bleeding, infertility (signs of 2º dysmenorrhea) Rule out underlying pelvic pathology and confirm cyclic nature of pain Pelvic examination not required; indicated for patients not responding to therapy or with signs of organic pathology</td>
<td>Bimanual exam: uterine or adnexal tenderness, fixed uterine retroflexion, uterosacral nodularity, pelvic mass, or enlarged irregular uterus (findings are rare in women &lt;30 yr) U/S, laparoscopy and hysteroscopy may be necessary to establish the diagnosis Vaginal and cervical cultures may be required</td>
</tr>
<tr>
<td><strong>Treatment</strong></td>
<td>Regular exercise, local heat NSAIDs: should be started before onset of pain Combined hormonal contraceptives with continuous or extended use: suppress ovulation/ reduce menstrual flow</td>
<td>Treat underlying cause</td>
</tr>
</tbody>
</table>

Endometriosis

Definition
- the presence of endometrial tissue (glands and stroma) outside of the uterine cavity
- chronic condition, resolving only with menopause

Etiology
- not fully understood; proposed mechanisms include (combination likely involved):
  - retrograde menstruation (Sampson’s theory)
  - immunologic: decreased NK cell activity limiting clearance of transplanted endometrial cells from pelvic cavity (may be due to decreased NK cell activity)
  - metaplasia of coelomic epithelium
  - extra pelvic disease may be due to aberrant vascular or lymphatic dissemination of cells
    - e.g., ovarian endometriosis may be due to direct lymphatic flow from uterus to ovaries

Epidemiology
- incidence: 15-30% of pre-menopausal women
- mean age at presentation: 25-30 yr
- regresses after menopause

Risk Factors
- family history (7-10x increased risk if affected 1st degree relative)
- obstructive anomalies of the genital tract (earlier onset) – resolves with treatment of anomaly
- nulliparity
- age >25 yr

Differential Diagnoses
- Chronic PID, recurrent acute salpingitis
- Hemorrhagic corpus luteum
- Benign/malignant ovarian neoplasm
- Ectopic pregnancy

Classic Triad of Endometriosis
- Dysmenorrhea
- Dyspareunia (cú-de-sac, uterosacral ligament)
- Dyschezia (uterosacral ligament, rectosigmoid attachment)
**Sites of Occurrence**
- ovaries: 60% patients have ovarian involvement
- broad ligament, vesicoperitoneal fold
- peritoneal surface of the cul-de-sac, uterosacral ligaments
- rectosigmoid colon, appendix
- rarely may occur in sites outside abdomen/pelvis, including lungs

**Clinical Features**
- may be asymptomatic and can occur with one of 3 presentations
  1. pain
     - menstrual symptoms
     - cyclic symptoms due to growth and bleeding of ectopic endometrium, usually precede menses (24-48 h) and continue throughout and after flow
     - secondary dysmenorrhea
     - sacral backache with menses
     - pain may eventually become chronic, worsening perimenstrually
     - deep dyspareunia
     - bowel and bladder symptoms
     - frequency, dysuria, hematuria
     - cyclic diarrhea/constipation, hematochezia, dyschezia (suggestive of deeply infiltrating disease)
  2. infertility
     - 30-40% of patients with endometriosis will be infertile
     - 15-30% of those who are infertile will have endometriosis
  3. mass (endometrioma)
     - ovarian mass can present with any of above symptoms or be asymptomatic
     - physical examination:
       - tender nodularity of uterine ligaments and cul-de-sac felt on rectovaginal exam
       - fixed retroversion of uterus
       - firm, fixed adnexal mass (endometrioma: an endometriotic cyst encompassing ovary)

**Investigations**
- definitive diagnosis can be made based on:
  - direct visualization of lesions typical of endometriosis at laparoscopy
  - biopsy and histologic exam of specimens (2 or more of: endometrial epithelium, glands, stroma, hemosiderin-laden macrophages)
  - laparoscopy
    - mulberry spots: dark blue or brownish-black implants on the uterosacral ligaments, cul-de-sac, or anywhere in the pelvis
    - endometrioma: “chocolate” cysts on the ovaries
    - “powder-burn” lesions on the peritoneal surface
    - early white lesions and clear blebs
    - peritoneal “pockets”
  - CA-125 (cancer antigen 125)
    - may be elevated in patients with endometriosis but should NOT be used as a diagnostic test

**Figure 8. SOGC guidelines for treatment of endometriosis**

**Treatment**
- surgical confirmation of disease is NOT required prior to starting medical management. Asymptomatic endometriosis does not require treatment. Management depends on certainty of the diagnosis, severity of symptoms, extent of disease, desire for future fertility, and impact to GI/GU systems (e.g. intestinal obstruction)
Adenomyosis

- synonym: “endometriosis interna” (uterine wall may be diffusely involved)

Epidemiology
- 15% of females >35 yr old; found in 20–40% of hysterectomy specimens
- mean age at presentation: 40–50 yr old (older age group than seen in endometriosis)
- adenomyosis is a common histologic finding in asymptomatic patients

Clinical Features
- often asymptomatic
- heavy menstrual bleeding, secondary dysmenorrhea, pelvic discomfort
- dyspareunia, dyschezia
- uterus symmetrically bulky, usually <14 cm
- Halban sign: tender, softened uterus on premenstrual bimanual exam

Investigations
- clinical diagnosis
- U/S or MRI can be helpful
- endometrial sampling to rule out other pathology

Treatment
- medical
  - iron supplements for anemia
  - analgesics, NSAIDs
  - Mirena" IUS
  - CHC, medroxyprogesterone (Depo-Provera") – limited evidence for efficacy
  - GnRH agonists (e.g. leuprolide (Lupron’))
  - low dose danazol 100-200 mg PO OD (trial x 4 mo)
- surgical
  - definitive: hysterectomy – treatment of choice in women who have completed childbearing

Fibroids

Epidemiology
- diagnosed in approximately 40–50% of pre-menopausal women >35 yr
- more common in African Americans, where they are also larger and occur at earlier age
- common indication for major surgery in females
- minimal malignant potential (1:1000)
- typically regress after menopause

Pathogenesis
- estrogen stimulates monoclonal smooth muscle proliferation
- progesterone stimulates production of proteins that inhibit apoptosis
- degenerative changes (occur when tumour outgrows blood supply)
  - fibroids can degenerate, become calcified, develop sarcomatous component, or obtain parasitic blood supply
Clinical Features
- majority asymptomatic (60%), often discovered as incidental finding on pelvic exam or U/S
- abnormal uterine bleeding (30%): dysmenorrhea, heavy menstrual bleeding
- pressure/bulk symptoms (20-50%)
  - pelvic pressure/heaviness
  - increased abdominal girth
  - urinary frequency and urgency
  - constipation, bloating (rare)
- acute urinary retention (extremely rare, but surgical emergency!)
- acute pelvic pain
- fibroid degeneration
- fibroid torsion (if pedunculated subserosal)
- infertility, recurrent pregnancy loss
- pregnancy complications (potential enlargement and increased pain, obstructed labour, difficult C-section)

Investigations
- bimanual exam: uterus asymmetrically enlarged, usually mobile
- CBC: anemia
- U/S: to confirm diagnosis and assess location of fibroids
- sonohysterogram: useful for differentiating endometrial polyps from submucosal fibroids, or for assessing intracavitary growth
- endometrial biopsy to rule out uterine cancer for abnormal uterine bleeding (especially if age >40 yr)
- occasionally MRI is used for pre-operative planning (e.g. before myomectomy)

Treatment
- only if symptomatic (heavy menstrual bleeding, menometrorrhagia, bulk symptoms), rapidly enlarging or intracavitary
- treat anemia if present
- conservative approach (watch and wait) if:
  - symptoms absent or minimal
  - fibroids <6-8 cm or stable in size
  - not submucosal (submucosal fibroids are more likely to be symptomatic)
  - currently pregnant due to increased risk of bleeding (follow-up U/S if symptoms progress)
- medical approach to treat AUB-L
  - antiprostaglandins (ibuprofen, other NSAIDs)
  - tranexamic acid (Cyklokapron™)
  - CHC, IUS or Depo-Provera™
  - GnRH agonist: leuprolide (Lupron™)
  - often used for 3 mo preoperatively to increase Hb and reduce fibroid size
  - reduces bleeding, shrinks fibroids, and corrects anemia
  - can be used long-term to bridge to menopause in combination with add-back progestin or estrogen
  - ulipristal acetate (Fibristal®): a selective progesterone receptor agonist
    - 5 mg daily for 3 mo
    - reduces bleeding, shrinks fibroids
    - repeat courses only if patient not eligible for surgery; patients must menstruate between courses
    - associated with benign, non-physiological endometrial changes (selective progesterone receptor modulator-associated endometrial changes (PAEC)) which are reversible with discontinuation of therapy
- note: rare side effect of liver failure. Screen for liver disease prior to prescribing, and monitor liver function before, during, and after treatment courses. Do not prescribe in patients with underlying liver disorder
- interventional radiology approach
  - uterine artery embolization (UAE) occludes both uterine arteries, shrinks fibroids by 50% at 6 mo; improves heavy bleeding in 90% of patients within 1-2 mo; not an option in women considering childbearing
  - higher risk of surgical re-intervention than with surgical approaches
- surgical approach
  - myomectomy (hysteroscopic, transabdominal, or laparoscopic)
  - hysteroscopic resection of fibroid and endometrial ablation for AUB-Lsm
  - hysterectomy (see Hysterectomy, GY6)
- note: avoid operating on fibroids during pregnancy (due to vascularity and potential pregnancy loss); expectant management usually best

Conclusions
- No significant differences in patient satisfaction or major complications in UAE compared to surgical intervention. UAE is associated with an increased risk of surgical re-intervention.

*Effectiveness: percentage of women reporting no pregnancy after 1 yr of use

Hormonal Methods

Combined Oral Contraceptive Pills
• progestin: prevents LH surge, suppresses ovulation, thickens cervical mucus, decreases tubal motility, decidualizes endometrium
• estrogen: suppresses FSH and follicular development, causes endometrial proliferation
• most contain low dose ethinyl estradiol (20-35 µg) plus progestin (norethinedrone, norgestrel, levonorgestrel, desogestrel, norgestimate, drospirenone)
• failure rate (0.3% to 8%) depending on compliance
• monophasic or triphasic formulations (varying amount of progestin throughout cycle)

Transdermal (Ortho Evra®)
• continuous release of 6 mg norelgestromin and 0.60 mg ethinyl estradiol into bloodstream
• applied to lower abdomen, back, upper arm, buttocks, NOT breast
• worn for 3 consecutive weeks (changed every wk) with 1 wk off to allow for menstruation
• as effective as OCP in preventing pregnancy (>99% with perfect use)
• may be less effective in women >90 kg
• may not be covered by drug plans

Contraceptive Ring (Nuva Ring®)
• thin flexible plastic ring; releases etonogestrel 120 µg/d and estradiol 15 µg/d
• works for 3 wk then removed for 1 wk to allow for menstruation
• as effective as OCP in preventing pregnancy (98%)
• side effects: vaginal infections/irritation, vaginal discharge
• may have better cycle control; i.e. decreased breakthrough bleeding

Summary: Risks of thromboembolism associated with combined OCPs were higher for drug preparations with newer progestrone types than for second generation drugs (levonorgestrel and norethisterone) and norgestimate.

Methods: Two nested case-control studies were performed on UK population through two large databases containing total of 1390 practices. Women aged 15-49 years with a first diagnosis of VTE in 2001-13 were matched with five controls by age, practice, and calendar year. OR for VTE incidence and use of combined OCPs were adjusted for smoking status, alcohol consumption, ethnic group, BMI, comorbidities, and other contraceptive drugs.

Results: Current exposure to OCP was associated with adjusted OR of 2.9 (95% CI 2.7-3.1) compared to no exposure in previous year. Risks associated with current exposure to new progesterone drug preparations (desogestrel, gestodene, drospirenone, cyproterone) were significantly higher than those for second generation contraceptives (levonorgestrel, norethisterone) and norgestimate.
Starting Hormonal Contraceptives

- thorough history and physical exam, including blood pressure and breast exam
- can start at any time during cycle but ideal if within 5 d of LMP
- follow-up visit 6 wk after hormonal contraceptives prescribed
- pelvic exam not required as STI screening can be done by urine and pap smear screening does not start until >21 yr

**SELECTED EXAMPLES OF PROGESTIN-ONLY METHODS**

**Progestin-Only Pill ("minipill")**
- Micronor® 0.35 mg norethindrone
- must be taken daily at same time of day to ensure reliable effect; no pill free interval
- higher failure rate (1.1-13%) with typical use, 0.51% with perfect use) than other hormonal methods
- ovulation inhibited only in 60% of women; most have regular cycles (but may cause oligo/amenorrhea)
- highly effective if also post-partum breastfeeding, or if >35 yr
- relies on the progestin effects on the cervical mucous and endometrial lining

**Depo-Provera®**
- injectable depot medroxyprogesterone acetate
- initiate ideally within 5 d of beginning of normal menses, immediately postpartum in breastfeeding and non-breastfeeding women. Can consider quick start
- irregular spotting progresses to complete amenorrhea in 70% of women (a/f after 1-2 yr of use)
- highly effective 99%; failure rate 0.3%
- suppresses ovulation very effectively
- side effect: decreased bone density (may be reversible) and weight gain
- disadvantage: restoration of fertility may take up to 9 mo

**Intrauterine Device**

<table>
<thead>
<tr>
<th>Mechanism of Action</th>
<th>Side Effects</th>
<th>Contraindications</th>
</tr>
</thead>
</table>
| Copper-Containing IUD (Nova-T®): mild foreign body reaction in endometrium; toxic to sperm and alters sperm motility | Both Copper and Progesterone IUD
  - Breakthrough bleeding
  - Expulsion (5% in the 1st yr, greatest in 1st mo and in nulliparous women)
  - Uterine wall perforation (1/1000) on insertion
  - If pregnancy occurs with an IUD, increased risk of ectopic pregnancy
  - Increased risk of PID (within first 10 d of insertion only) | Absolute
  - Both Copper and Progesterone IUD
  - Known or suspected pregnancy
  - Undiagnosed genital tract bleeding
  - Acute or chronic PID
  - Lifestyle risk for STIs* |
| Progesterone-Releasing IUS (Mirena®, Kyleena®, Jaydess®): decidualization of endometrium and thickening of cervical mucus; minimal effect on ovulation
  - Highly effective (95-99%); failure rate 0-1.2%
  - Contraceptive effects last 5 yr
  - Reversible, private, convenient
  - May be used in women with contraindications to OCPs or wanting long-term contraception | Copper IUD: increased blood loss and duration of menses, dysmenorrhea | Relative
  - Both Copper and Progesterone IUD
  - Valvular heart disease
  - Past history of PID or ectopic pregnancy
  - Presence of prosthesis
  - Abnormalities of uterine cavity, intracavitary fibroids
  - Cervical stenosis
  - Immunosuppressed individuals (e.g. HIV) |
| Progesterone IUD: bloating, headache | Copper IUD: severe dysmenorrhea or heavy menstrual bleeding | |

*Cervical swabs for gonorrhea and chlamydia should be done prior to insertion

---

**Continuous or Extended Cycle vs. Cyclic Use of Combined Hormonal Contraceptives for Contraception (Cochrane Lib Rev 2014)**

**Purpose:** Systematic review of RCTs assessing the efficacy and side effects of cyclic administration vs. extended use (longer periods placebo) or continuous use ( uninterrupted active pill administration) of combination oral contraceptives (COCs).

**Results:** The initial review published in 2012 identified 12 RCTs that ultimately showed no difference between groups with regards to efficacy (pregnancy rates), safety, and compliance rates. Continuous or extended COCs were shown to reduce menstrual symptoms (headaches, breast pain, bloating, and menstrual pain). In addition, 11 of 12 studies reported similar or improved bleeding patterns with continuous or extended cycles.

**Conclusions:** This recently published updated systematic review identified a further 4 RCTs, however, results did not change.
**Emergency Postcoital Contraception**

</tbody>
</table>

Follow-up

• 3-4 wk post treatment to confirm efficacy (confirmed by spontaneous menses or pregnancy test)
• contraception counselling

**Termination of Pregnancy**

**Indications**

• patient desires an end to pregnancy
• may be for medical reasons (mother or fetus unhealthy) or social reasons, including patient request

**Legal Issues**

• no current law in Canada concerning abortion therefore considered legal at any gestational age
• CPSO: a physician must refer for abortion services regardless of personal beliefs, but not compelled to perform procedure

**Rates**

• 13.1 abortions/1000 women aged 15-44 in Canada (2017 CIHI data)
• worldwide: 42 million induced abortions per year; half are unsafe (WHO data)
• maternal mortality almost zero where induced abortion is safe and legal; rises to 100 maternal deaths/100,000 live births in sub-Saharan Africa and other countries where abortion is illegal and unsafe
• in Canada, 91% of induced abortions occur <12 wk GA; very rare after 24 wk (usually only for maternal/fetal reasons)

**Methods of induced abortion**

• medical
  • gold standard up to 9 wk GA: mifepristone and misoprostol: 95-98% effective
  • mifepristone blocks the progesterone receptor (progesterone required in early pregnancy)
  • misoprostol induces uterine contractions
  • can also use misoprostol alone or methotrexate and misoprostol (with lower success rates of 90-95%)
  • side effects: bleeding (self-limited) and pain (while tissue passes) are expected side effects

There is no association between termination of pregnancy and either future breast cancer or future development of psychiatric disease
Pregnancy-Related Complications

First and Second Trimester Bleeding

Approach to the Patient with Bleeding in T1/T2

History
- risk factors for ectopic pregnancy (see Ectopic Pregnancy, GY20)
- previous spontaneous abortion
- recent trauma
- characteristics of the bleeding (including any tissue passed)
- characteristics of the pain (cramping pain suggests spontaneous abortion)
- history of coagulopathy
- gynecological/obstetric history
- fatigue, dizziness, syncopal episodes due to hypovolemia, fever (may be associated with septic abortion)

Physical
- vitals (including orthostatic changes)
- abdomen (symphysis fundal height, tenderness, presence of contractions)
- perineum (signs of trauma, genital lesions)
- speculum exam (cervical os open or closed, presence of active bleeding/clots/tissue)
- pelvic exam (uterine size, adnexal mass, uterine/adnexal tenderness, cervical motion tenderness)

Investigations
- β-hCG (may be lower than expected for GA in spontaneous abortion, can be used to diagnose viable pregnancy vs. ectopic pregnancy vs. abortion)
- U/S (confirm intrauterine pregnancy and fetal viability)
- CBC
- group and screen

Treatment
- IV resuscitation for hemorrhagic shock
- treat the underlying cause

Surgical
- <14 wk:
  - manual vacuum aspiration – up to about 8-9 wk with hand held aspiration device
  - suction dilatation + aspiration ± curettage – may involve pre-surgical preparation of cervix with laminaria tents and/or misoprostol
- 14-24 wk: dilatation and evacuation; pre-surgical preparation of cervix required with laminaria tents
- pain or discomfort during procedure mitigated by use of appropriate analgesia/sedation/anesthesia (including paracervical blocks)
- rare complications (1-5%): laceration of cervix, infection/endometritis, retained products of conception, ongoing pregnancy
- very rare complications (0.1-2%): hemorrhage, perforation of uterus, Asherman’s syndrome (adhesions within the endometrial cavity causing amenorrhea/infertility), future preterm birth (controversial and likely only with repeated abortion)

Counselling
- options counselling always provided; always offer possibility of carrying pregnancy with/without adoption
- offer future contraception and family planning services
- ensure follow-up

Every woman of childbearing age presenting to ER with abdominal or pelvic pain should have β-hCG measured
Spontaneous Abortions

- see Termination of Pregnancy for therapeutic abortions, GY18

</tbody>
</table>

Ectopic Pregnancy

Definition
- embryo implants outside of the endometrial cavity

Epidemiology
- 1/100 pregnancies
- fourth leading cause of maternal mortality, leading cause of maternal death in first trimester
- increase in incidence over the last 3 decades
- three commonest locations for ectopic pregnancy: ampullary (70%), isthmic (12%), fimbrial (11%) > ovarian (5%) > interstitial (2%) > abdominal (1%)

Etiology
- 50% due to damage of fallopian tube cilia following PID
- intrinsic abnormality of the fertilized ovum
- conception late in cycle
- transmigration of fertilized ovum to contralateral tube
Ectopic Pregnancy

**Risk Factors**
- previous ectopic pregnancy
- gynecologic
  - current IUD use – increased risk of ectopic if pregnancy occurs
  - history of PID (especially infection with C. trachomatis), salpingitis
  - infertility
  - infertility treatment (IVF pregnancies following ovulation induction (7% ectopic rate))
  - previous procedures
    - any surgery on fallopian tube (for previous ectopic, tubal ligation, etc.)
    - abdominal surgery for ruptured appendix, etc.
- smoking
- structural
  - uterine leiomyomas
  - adhesions
  - abnormal uterine anatomy (e.g. T-shaped uterus)

**Investigations**
- serial β-hCG levels; normal doubling time with intrauterine pregnancy is 1.6-2.4 d in early pregnancy
  - rise of <20% of β-hCG (1.6-2.4 d) is 100% predictive of a non-viable pregnancy
  - prolonged doubling time, plateau, or decreasing levels before 8 wk implies nonviable gestation but does not provide information on location of implantation
  - 85% of ectopic pregnancies demonstrate abnormal β-hCG doubling
- ultrasonound
  - U/S is only definitive if fetal cardiac activity is detected in the tube or uterus
  - specific finding on transvaginal U/S is a tubal ring
  - suspect ectopic in case of empty uterus by TVUS with β-hCG >2000-3000 mIU/ml
  - laparoscopy (sometimes used for definitive diagnosis)

**Treatment**
- goals of treatment: conservative (preserve tube if possible), maintain hemodynamic stability
- surgical = laparoscopy
  - linear salpingostomy an option if tube salvageable, however, patient must be reliable to follow-up with weekly β-hCG
  - salpingectomy if tube damaged or ectopic is ipsilateral recurrence
  - 15% risk of persistent trophoblast if salpingectomy; must monitor β-hCG titres weekly until they reach non-detectable levels
  - consider Rhogam® if Rh negative
  - patient may require laparotomy if unstable, extensive abdominal surgical history, etc.
- medical = methotrexate
  - use 50 mg/m² body surface area; given in a single IM dose
  - this is 1/5 to 1/6 chemotherapy dose, therefore minimal side effects (reversible hepatic dysfunction, diarrhea, gastritis, dermatitis)
  - follow β-hCG levels weekly until β-hCG is non-detectable
  - plateaued or rising levels suggest persistent trophoblastic tissue requiring further treatment

**Figure 11. Algorithm for suspected ectopic pregnancy**

**Suspected Ectopic Pregnancy**
1. Positive urine β-hCG; 2. Abdominal pain; 3. Vaginal bleeding

**Hemodynamically stable**
- Transvaginal U/S
- Serum β-hCG

- Intraterine pregnancy
  - β-hCG level low and declining
  - AND no fetal heartbeat or extraterine sac suspicious for ectopic pregnancy
  - AND patient is reliable for follow-up

- <3.5 cm unruptured ectopic
  - AND no fetal heart rate
  - AND β-hCG <5,000
  - AND no hepatic/renal/hematological disease
  - AND compliance assured
  - AND able and willing to follow-up

- Expectant management

- Methotrexate

- Surgery

**Hemodynamically unstable or suspicion of impeding/ongoing ruptured ectopic**
- Surgery

**DDx of Lower Abdominal Pain**
- Urinary tract: UTI, kidney stones
- GI: diverticulitis, appendicitis
- Gyne: endometriosis, PID, fibroid (degenerating, infarcted, torsion), ovarian torsion, ovarian neoplasm, ovarian cyst, pregnancy-related

Any woman presenting with abdominal pain, vaginal bleeding and amenorrhea is an ectopic pregnancy until proven otherwise

More than half of patients with ectopic pregnancy have no risk factors

**Presentation of Ectopic Pregnancy Ruptures**
- Acute abdomen with increasing pain
- Abdominal distention
- Shock

**Contraindications to Methotrexate Therapy for Ectopic Pregnancy**
- Abnormalities in hematologic, hepatic or renal function
- Immunodeficiency
- Active pulmonary disease
- Peptic ulcer disease
- Hypersensitivity to methotrexate
- Heterotopic pregnancy with coexisting viable intrauterine pregnancy
- Breastfeeding
- Unwilling or unable to adhere to methotrexate protocol

**Management of Abortions**
- Always rule out an ectopic
- Always check Rh; if negative, give Rhogam®
- Always ensure patient is hemodynamically stable
Infertility

Epidemiology
- 10-15% of couples, must investigate both members of the couple

Female Factors
Etiology
- ovulatory dysfunction (15-20%)
  - hypothalamic (hypothalamic amenorrhea)
    - stress, poor nutrition, excessive exercise (even with presence of menstruation), history of eating disorders
  - pituitary (prolactinoma, hypopituitarism)
  - ovarian
    - PCOS
    - primary ovarian insufficiency
    - luteal phase defect (poor follicle production, premature corpus luteum failure, failed uterine lining response to progesterone), poorly understood
  - systemic diseases (thyroid, Cushing's syndrome, renal/hepatic failure), diabetes
  - congenital (Turner's syndrome, gonadal dysgenesis, or gonadotropin deficiency)
- outflow tract abnormality (15-20%)
  - tubal factors (20-30%)
    - PID
    - adhesions (previous surgery, peritonitis, endometriosis)
    - ligation/occlusion (e.g. previous ectopic pregnancy)
  - uterine factors (<5%)
    - congenital anomalies, bicornuate uterus, septate uterus, prenatal DES exposure, intrauterine adhesions (e.g. Asherman's syndrome), fibroids/polyps (particularly intrauterine)
    - infection (endometritis, pelvic tuberculosis)
    - endometrial ablation
    - cervical factors (5%)
    - hostile or acidic cervical mucus, anti-sperm antibodies
    - structural defects (cone biopsies, laser or cryotherapy)
- endometriosis (15-30%)
- multiple factors (30%)
- unknown factors (10-15%)

Investigations
- ovulatory
  - day 3: FSH, LH, TSH, prolactin ± DHEA, free testosterone (if hirsute) add estradiol for proper FSH interpretation
  - day 21-23: serum progesterone to confirm ovulation
  - initiate basal body temperature monitoring (biphasic pattern)
  - postcoital test: evaluate mucus for clarity, pH, spinnbarkeit/fibrosity (rarely done)
- tubal factors
  - HSG (can be therapeutic – opens fallopian tube)
  - SHG (can be therapeutic; likely less – opens fallopian tube)
  - laparoscopy with dye insufflation (or tubal dye test) rarely done as diagnostic
- peritoneal/uterine factors
  - HSG/SHG, hysteroscopy
- other
  - karyotype

When Should Investigations Begin?
- <35 yr: after 1 yr of regular unprotected intercourse
- 35-40 yr: after >6 mo
- >40 yr: immediately
- Earlier if
  - History of PID
  - History of infertility in previous relationship
  - Prior pelvic surgery
  - Chemotherapy/radiation in either partner
  - Recurrent pregnancy loss
  - Moderate-severe endometriosis

Ethical Considerations in Infertility Treatment
- Infertility demands non-judgmental discussion
- Ethical issues surrounding therapeutic donor insemination in same sex couples, surrogacy, donor gametes, and other advanced reproductive technologies are still evolving and remain controversial
- If the doctor finds that certain treatment options lie outside of their moral boundaries, the infertile couple should be referred to another physician
**Polycystic Ovarian Syndrome**

**Treatment**
- **education**: timing intercourse relative to ovulation (from 2 d prior to 2 d following presumed ovulation), every other day
- **medical**
  - ovulation induction
    - clomiphene citrate (Clomid®): estrogen antagonist causing a perceived decreased estrogen state, resulting in increased pituitary gonadotropins; which increases FSH and LH and induces ovulation (better results if anovulatory)
    - followed by β-hCG for stimulation of ovum release
    - Letrozole: aromatase inhibitor. May be associated with a higher rate of live births in patients with PCOS
  - may add:
    - bromocriptine (dopamine agonist) if elevated prolactin
    - dexamethasone for hyperandrogenism (adult onset congenital adrenal hyperplasia)
    - metformin (for PCOS)
    - luteal phase progesterone supplementation for luteal phase defect (mechanism not completely understood)
    - anticoagulation and ASA (81 mg PO OD) for women with a history of recurrent spontaneous abortions (for antiphospholipid antibody syndrome)
    - thyroid replacement to keep TSH <2.5
  - **surgical/procedural**
    - tubuloplasty
    - lysis of adhesions
    - artificial insemination: intracervical insemination (ICI), intrauterine insemination (IUI), intratubal insemination (ITI)
    - sperm washing
    - IVF (fertilization)
    - IFT (intrafallopian transfer)
    - GIFT* (gamete intrafallopian transfer): immediate transfer with sperm after oocyte retrieval
    - ZIFT* (zygote intrafallopian transfer): transfer after 24 h culture of oocyte and sperm
    - TET* (tubal embryo transfer): transfer after >24 h culture
    - ICSI (intracytoplasmic sperm injection)
    - IVM (in vitro maturation)
    - ± oocyte or sperm donors
    - ± pre-genetic screening for single gene defects in karyotype of zygote
  * not performed in Canada

**Male Factors**
- see Urology, U36

**Etiology**
- varicocele (>40%)
- idiopathic (>20%)
- obstruction (~15%)
- cryptorchidism (~8%)
- immunologic (~3%)

**Investigations**
- semen analysis and culture
- postcoital (Huhner) test: rarely done

**Polycystic Ovarian Syndrome**
- also called chronic ovarian androgenism

**Etiology**

```plaintext
↑ estrogen
↑ peripheral conversion to estrogen
↑ ovarian secretion of androgens
↑ LH secretion
↑ FSH secretion
↓ Insulin
↓ Anovulation
↓ Oligomenorrhea
↓ Hirsutism
↓ Infertility
↓ Obesity
```

*Figure 12. Pathophysiology of polycystic ovarian syndrome*
Polycystic Ovarian Syndrome

**Diagnosis**
- Rotterdam diagnostic criteria: 2 of 3 required
  - oligomenorrhea/irregular menses for 6 mo
  - hyperandrogenism
    - clinical evidence - hirsutism or acne
    - biochemical evidence - raised free testosterone
  - polycystic ovaries on U/S (not appropriate in adolescents)

**Clinical Features**
- average age 15-35 yr at presentation
- in adolescents, wait at least 1-2 yr to make diagnosis as adolescence resembles PCOS
- abnormal/irregular uterine bleeding, hirsutism, infertility, obesity, virilization
- acanthosis nigricans: browning of skin folds in intertriginous zones (indicative of insulin resistance)
- insulin resistance occurs in both lean and obese patients
- family history of DM

**Investigations**
- goal: identify hyperandrogenism or chronic anovulation and rule out specific pituitary or adrenal disease as the cause
- laboratory
  - prolactin, 17-hydroxyprogesterone, free testosterone, DHEA-S, TSH, free T4, androstenedione, SHBG
  - LH:FSH > 2:1; LH is chronically high with FSH mid-range or low (low sensitivity and specificity)
  - increased DHEA-S, androstenedione and free testosterone (most sensitive), decreased SHBG
- transvaginal or transabdominal U/S: polycystic-appearing ovaries (“string of pearls” – 12 or more small follicles 2-9 mm, or increased ovarian volume)
- tests for insulin resistance or glucose tolerance
  - fasting glucose:insulin ratio < 4.5 is consistent with insulin resistance (U.S. units)
  - 75 g OGTT yearly (particularly if obese)
- laparoscopy
  - not required for diagnosis
  - most common to see white, smooth, sclerotic ovaries with a thick capsule; multiple follicular cysts in various stages of atresia; and hyperplastic theca and stroma
- rule out other causes of abnormal bleeding

**Treatment**
- cycle control
  - lifestyle modification (decrease BMI, increase exercise) to decrease peripheral estrone formation
  - OCP monthly or cyclic Provera® to prevent endometrial hyperplasia due to unopposed estrogen
  - oral hypoglycemic (e.g. metformin) if type 2 diabetic or if trying to become pregnant
  - tranexamic acid (Cyklokapron®) for menorrhagia only
- infertility
  - medical induction of ovulation: letrozole, clomiphene citrate (no longer available in Canada), human menopausal gonadotropins (HMG [Pergonal®]), LH-RH, recombinant FSH, and metformin
  - metformin may be used alone or in conjunction with clomiphene citrate for ovulation induction
  - ovarian drilling (perforate the stroma), wedge resection of the ovary
  - bromocriptine (if hyperprolactinemia)
- hirsutism
  - any OCP can be used
  - Diane 35® (cyproterone acetate): antiandrogenic
  - Yasmin® (drospirenone and ethinyl estradiol): spironolactone analogue (inhibits steroid receptors)
  - mechanical removal of hair
  - finasteride (5-α reductase inhibitor)
  - flutamide (androgen reuptake inhibitor)
  - spironolactone: androgen receptor inhibitor

**Insulin-Sensitising Drugs (metformin, rosiglitazone, pioglitazone, D-chiro-inositol)** for Women with Polycystic Ovary Syndrome, Oligo Amenorrhea and Subfertility

**Cochrane Database Syst Rev 2012; (5):CD003053**

**Purpose:** To evaluate efficacy of insulin-sensitising drugs in improving reproductive outcomes of women with PCOS.

**Methods:** 42 RCTs (n=3992) were included.

**Conclusions:** Metformin was associated with improved clinical pregnancy rates whether used alone or in combination with clomiphene. However, this did not translate into live birth rates.

**PCOS May be Confused with**
- Late onset congenital adrenal hyperplasia (21-hydroxylase deficiency)
- Cushing’s syndrome
- Ovarian and adrenal neoplasms
- Hyperprolactinemia
- Hypothyroidism

**Clinical Signs of Endocrine Imbalance**
- Menstrual disorder/amenorrhea (80%)
- Infertility (14%)
- Hirsutism (89%)
- Obesity (49%)
- Impaired glucose tolerance (25%)
- DM (10%)

**Long-Term Health Consequences**
- Hyperlipidemia
- Adult-onset DM
- Endometrial hyperplasia
- Infertility
- Obesity
- Sleep apnea

**Diagnostic Criteria for Polycystic Ovary Syndrome: Pitfalls and Controversies**
JOGC 2008;8:671-679

At present, there is no clear-cut definition of biochemical hyperandrogenemia, particularly since there is dependence on poor laboratory standards for measuring androgens in women. Clinical signs of hyperandrogenism are ill-defined in women with PCOS, and diagnosis of both hirsutism and polycystic ovarian morphology remains subjective. There is also the inappropriate tendency to assign ovulatory status solely on basis of menstrual cycle history or poorly timed endocrine measurements. Therefore it is important as clinicians to recognize the multi-factorial and complex nature of PCOS and place this in the context of our present diagnostic limitations.
**Gynecological Infections**

### Physiologic Discharge

- clear, white, flocculent, odourless discharge; pH 3.8-4.2
- smear contains epithelial cells, Lactobacilli
- increases with increased estrogen states: pregnancy, OCP, mid-cycle, PCOS, or premenarchal
- if increased in perimenopausal/postmenopausal woman, consider investigation for other effects of excess estrogen (e.g. endometrial cancer)

### Pruritus

- can be caused by physiologic discharge and cervical mucus production
- non-physiologic
  - genital tract infection
  - vulvovaginitis: candidiasis, trichomoniasis, BV, polymicrobial superficial infection
  - chlamydia, gonorrhea
  - pyosalpinx, salpingitis
  - genital tract inflammation (non-infectious)
  - local: chemical irritants, douches, sprays, foreign body, trauma, atrophic vaginitis, desquamative inflammatory vaginitis, focal vulvitis
  - neoplasia: vulvar, vaginal, cervical, endometrial
  - systemic: toxic shock syndrome, Crohn's disease, collagen disease, dermatologic (e.g. lichen sclerosis)
  - IUD, OCP (secondary to progesterone)

### Vulvovaginitis

**PREPUBERTAL VULVOVAGINITIS**

- clinical features: irritation, pruritus, discharge, vulvar erythema, vaginal bleeding (specifically due to Group A Streptococci and Shigella)
- etiology
  - poor hygiene (proximity of anus to vagina)
  - foreign bodies (most commonly tissue paper)
  - irritation by perfumed soaps, chemicals, and tight clothing
  - localized skin disorders: lichen sclerosis, condyloma acuminata
  - trauma: accidental straddle injury, sexual abuse
  - infectious
    - pinworms
    - Candida (if using diapers or chronic antibiotics)
    - Group A streptococcus, S. aureus and Shigella
    - discovery of STI should raise suspicion of sexual abuse
  - other
    - polyps, tumour (ovarian malignancy)
    - psychosomatic vaginal complaints (specific to vaginal discharge)
    - endocrine abnormalities (specific to vaginal bleeding)
    - blood dyscrasia (specific to vaginal bleeding)
- investigations
  - vaginal swab for culture (specifically state that it is a pre-pubertal specimen)
  - pH, wet-mount, and KOH smear in prepubertal adults only
- treatment
  - enhanced hygiene and local measures (handwashing, white cotton underwear, no nylon tights, no tight fitting clothes, no sleeper pajamas, sitz baths, avoid bubble baths, use mild detergent, eliminate fabric softener, avoid prolonged exposure to wet bathing suits, urination with legs spread apart)
  - A&D® dermatological ointment (vitamin A/D) to protect vulvar skin
  - infectious: treat with antibiotics for organism identified

### Table 14. Other Common Causes of Vulvovaginitis in Prepubertal Girls

**Vulvovaginitis**

Vulvar and vaginal inflammation

**Prepubertal and Adolescent Gynecological Infections: Legal Aspects of Confidentiality**

- Clinicians who treat adolescents must be aware of federal, state, and provincial laws related to adolescent consent and confidentiality
- Clinicians must be aware of guidelines governing funding sources for particular services and be familiar with the consent and confidentiality policies of the facility in which they practice

**There is no high quality evidence showing a link between vulvovaginal candidiasis and hygienic habits or wearing tight or synthetic clothing**

**Most common gynecological problem in prepubertal girls is non-specific vulvovaginitis, not yeast**
**INFECTIOUS VULVOVAGINITIS**

**Table 15. Infectious Vulvovaginitis**

</table>

**Discharge**

- Whitish, “cottage cheese,” minimal
- Grey, thin, diffuse
- Yellow-green, malodorous, diffuse, frothy

**Other**

- 20% asymptomatic
- 50-75% asymptomatic
- 25% asymptomatic

**Signs/Symptoms**

- Intense pruritus
- Swollen, inflamed genitals
- Vulvar burning, dysuria, dyspareunia
- Fishy odour, especially after coitus
- Absence of vulvar/vaginal irritation
- Occasionally irritated, tender vulva
- Dysuria, frequency
- Petechiae on vagina and cervix
- Absence of vulvar/vaginal irritation
- Fishy odour with addition of KOH to slide (due to formation of amines)
- Motile flagellated organisms
- Inflammatory cells (PMNs)
- Can have positive whiff test

**pH**

- ≤4.5
- ≥4.5
- ≥4.5

**Saline Wetmount**

- KOH wetmount reveals hyphae and spores
- >20% clue cells = squamous epithelial cells dotted with coccobacilli (Gardnnerella)
- Paucity of WBC
- Paucity of Lactobacilli
- Positive whiff test: fishy odour with addition of KOH to slide (due to formation of amines)
- Motile flagellated organisms
- Inflammatory cells (PMNs)
- Can have positive whiff test

**Treatment**

- No treatment if non-pregnant and asymptomatic, unless scheduled for pelvic surgery or procedure
- Oral Metronidazole 500 mg PO bid x 7 d
- Topical Metronidazole gel 0.75% x 5 d OD
- Clindamycin 2% 5 g intravaginally at bedtime for 7 d
- Probiotics (Lactobacillus sp.): oral or topical alone or as adjuvant
- Treatment even if asymptomatic
- Metronidazole 2 g PO single dose or 500 mg bid x 7 d (alternative)
- Symptomatic pregnant women should be treated with 2 g metronidazole once
- Prophylaxis for recurrent infection includes boric acid, vaginal suppositories, luteal phase
- Routine treatment of partner(s) not recommended (not sexually transmitted)
- Associated with recurrent preterm labour, preterm birth, and postpartum endometritis
- Need to warn patients on metronidazole not to consume alcohol (disulfiram-like action)
- Routine treatment of partner(s) not recommended (not sexually transmitted)
- Warnings accompanying metronidazole use
- Treatment partner(s) (sexually transmitted)

**Other**

- Sexually Transmitted Infections
- see Family Medicine, FM42

**Sexually Transmitted Infections**

- Chancroid
- Chlamydia
- Gonorrhea
- Hepatitis A, B, C
- HIV
- Syphilis

**CDC Notifiable Diseases**

- Chancroid
- Chlamydia
- Gonorrhea
- Hepatitis A, B, C
- HIV
- Syphilis

**Risk Factors for STIs**

- History of previous STI
- Contact with infected person
- Sexually active individual <25 yr
- Multiple partners
- New partner in last 3 mo
- Lack of barrier protection use
- Street involvement (homelessness, drug use)
TRICHOMONIASIS
• see Infectious Vulvovaginitis

CHLAMYDIA

Etiology
• Chlamydia trachomatis

Epidemiology
• most common bacterial STI in Canada
• often associated with N. gonorrhoeae

Clinical Features
• asymptomatic (80% of women)
• muco-purulent endocervical discharge
• urethral syndrome: dysuria, frequency, pyuria, no bacteria on culture
• pelvic pain
• postcoital bleeding or intermenstrual bleeding (particularly if on OCP and prior history of good cycle control)
• symptomatic sexual partner

Investigations
• cervical culture or nucleic acid amplification test (can present in pharynx, rectum)
• obligate intracellular parasite: tissue culture is the definitive standard
• urine and self vaginal tests now available, which are equally or more effective than cervical culture

Treatment
• doxycycline 100 mg PO bid for 7 d or azithromycin 1 g PO in a single dose. Doxycycline is contraindicated in the 2nd and 3rd trimesters of pregnancy
• also treat gonorrhea because of high rate of co-infection
• reportable disease, partners should also be referred for treatment
• test of cure for chlamydia required in pregnancy (cure rates lower in pregnant patients) → retest 3-4 wk after initiation of therapy

Screening
• high-risk groups
• during pregnancy
• when initiating OCP if sexually active (independent risk factor)

Complications
• PID: low-grade salpingitis and adhesions resulting in tubal obstruction
• infertility
• ectopic pregnancy
• chronic pelvic pain
• Fitz-Hugh-Curtis syndrome (liver capsule inflammation)
• reactive arthritis (male predominance, HLA-B27 associated), conjunctivitis, urethritis
• perinatal infection: conjunctivitis, pneumonia

GONORRHEA

Etiology
• Neisseria gonorrhoeae
• symptoms and risk factors same as chlamydia

Investigations
• Gram stain shows Gram-negative intracellular diplococci
• cervical, rectal, and throat culture (if clinically indicated)

Treatment
• single dose of ceftriaxone 250 mg IM plus azithromycin 1 g PO
• if pregnant: above regimen or 2 g spectinomycin IM plus azithromycin 1 g PO (avoid quinolones)
• also treat chlamydia, due to high rate of co-infection
• treat partners
• reportable disease
• screening as with chlamydia
HUMAN PAPILLOMAVIRUS

Etiology
- most common viral STI in Canada
- >200 subtypes, of which >30 are genital subtypes
- HPV types 6 and 11 are classically associated with anogenital warts/condylomata acuminata
- HPV types 16 and 18 are the most oncogenic (classically associated with cervical HSIL)
- types 16, 18, 31, 33, 35, 36, 45 (and others) associated with increased incidence of cervical and vulvar intraepithelial hyperplasia and carcinoma

Clinical Features
- latent infection
  - no visible lesions, asymptomatic
  - only detected by DNA hybridization tests
- subclinical infection
  - visible lesion found during colposcopy or on Pap test
- clinical infection
  - visible wart-like lesion without magnification (check pharynx too)
  - hyperkeratotic, verrucous or flat, macular lesions
  - vulvar edema

Investigations
- cytology
  - koilocytosis: nuclear enlargement and atypia with perinuclear halo
  - biopsy of lesions at colposcopy
  - detection of HPV DNA subtype using nucleic acid probes (not routinely done but can be done in presence of abnormal Pap test to guide treatment)

Treatment
- patient administered
  - podofilox 0.5% solution or gel bid x 3 d in a row (4 d off) then repeat x 4 wk
  - imiquimod (Aldara”) 5% cream 3x/wk qhs x 16 wk
- provider administered
  - cryotherapy with liquid nitrogen: repeat q1-2wk
  - podophyllin resin in tincture of benzoin: weekly
  - trichloroacetic acid (TCA) (80-90%) or bichloroacetic acid weekly x 4-6 wk; safe in pregnancy
  - surgical removal/laser
  - intralesional interferon

Prevention
- vaccination: Gardasil®9, Gardasil®, Cervarix® (see Table 28, GY45)
- condoms may not fully protect (areas not covered, must be used every time throughout entire sexual act)

HERPES SIMPLEX VIRUS OF VULVA

Etiology
- 90% are HSV-2, 10% are HSV-1

Clinical Features
- may be asymptomatic
- initial symptoms: present 2-21 d after contact
- prodromal symptoms: tingling, burning, pruritus
- multiple, painful, shallow ulcerations with small vesicles appear 7-10 d after initial infection (absent in many infected persons); lesions are infectious
- inguinal lymphadenopathy, malaise, and fever often with first infection
- dysuria and urinary retention if urethral mucosa affected
- recurrent infections: less severe, less frequent, and shorter in duration (usually only HSV-2)

Investigations
- viral culture preferred in patients with ulcer present; however decreased sensitivity as lesions heal
- cytologic smear (Tzanck smear) shows multinucleated giant cells, acidophilic intranuclear inclusion bodies
- HSV DNA PCR
- type specific serologic tests for antibodies to HSV-1 and HSV-2 (not available routinely in Canada)
**Treatment**

- first episode: acyclovir 200 mg PO five times daily x 7-10 d, or famciclovir 250 mg PO tid x 7-10 d or valacyclovir 1 g PO bid x 7-10 d
- recurrent episode: acyclovir 400 mg PO tid x 5 d, valacyclovir 1 g PO OD x 5 d or famciclovir 250 mg PO BID x 5 d
- daily suppressive therapy
  - consider for >6 recurrences per yr or recurrence every 2 mo
  - acyclovir 400 mg PO bid or valacyclovir 500 mg PO OD or valacyclovir 1 g PO OD or famciclovir 250 mg PO bid
- severe disease: IV acyclovir 5-10 mg/kg IV q8h x 2-7 d or until clinical improvement observed followed by oral antiviral therapy to complete 10 d of therapy total
- education regarding transmission: avoid sexual contact from onset of prodrome until lesions have cleared, use barrier contraception

**SYPHILIS**

**Etiology**
- *Treponema pallidum*

**Classifications**
- primary syphilis
  - 3-4 wk after exposure
  - painless chancr on vulva, vagina, or cervix
  - painless inguinal lymphadenopathy
  - serological tests usually negative, local infection only
- secondary syphilis (can resolve spontaneously)
  - 2-6 mo after initial infection
  - nonspecific symptoms: malaise, anorexia, headache, diffuse lymphadenopathy
  - generalized maculopapular rash: palms, soles, trunk, limbs
  - condylomata lata: anogenital, broad-based, fleshy, grey lesions
  - serological tests usually positive
- latent syphilis
  - no clinical manifestations; detected by serology only
- tertiary syphilis
  - may involve any organ system
  - neurological: tabes dorsalis, general paresis
  - cardiovascular: aortic aneurysm, dilated aortic root
  - vulvar gumma: nodules that enlarge, ulcerate, and become necrotic (rare)
- congenital syphilis
  - may cause fetal anomalies, stillbirths, or neonatal death

**Investigations**
- aspiration of ulcer serum or node
- darkfield microscopy (most sensitive and specific diagnostic test for syphilis): look for spirochetes
- non-treponemal screening tests (VDRL, RPR); non-reactive ater treatment, can be positive with other conditions
- specific anti-treponemal antibody tests (FTA-ABS, MHA-TP, TP-PA)
  - confirmatory tests; remain reactive for life (even after adequate treatment)

**Treatment**
- reportable disease, partners should be referred for treatment
- treatment of primary, secondary, latent syphilis of <1 yr duration
  - benzathine penicillin G 2.4 million units IM single dose
- treatment of latent syphilis of >1 yr duration
  - benzathine penicillin G 2.4 million units IM q1wk x 3 wk
- treatment of neurosyphilis
  - IV aqueous penicillin G 3-4 million units IM q4h x 10-14 d
- screening
  - high-risk groups
  - in pregnancy (see Obstetrics, Infections During Pregnancy, OB29)

**Complications**
- if untreated, 1/3 will experience late complications

**HIV**
- see Infectious Diseases, ID25
Bartholin Gland Abscess

Etiology
- often anaerobic and polymicrobial
- *U. urealyticum*, *N. gonorrhoeae*, *C. trachomatis*, *E. coli*, *P. mirabilis*, *Streptococcus* spp., *S. aureus* (rare)
- blockage of duct

Clinical Features
- unilateral swelling and pain in inferior lateral opening of vagina
- sitting and walking may become difficult and/or painful

Treatment
- sitz baths, warm compresses
- antibiotics: cephalaxin x 1 wk
- incision and drainage using local anesthesia with placement of Word catheter (10 French latex catheter) for 2-3 wk (or as long as stays in situ)
- marsupialization under general anesthetic: more definitive treatment
- rarely treated by removing gland

Pelvic Inflammatory Disease

- up to 20% of all gynecology-related hospital admissions
- inflammation of the upper genital tract (above the cervix) including endometrium, fallopian tubes, ovaries, pelvic peritoneum ± contiguous structures

Etiology
- causative organisms (in order of frequency)
  - *C. trachomatis*
  - *N. gonorrhoeae*
  - gonorrhea and chlamydia often co-exist
  - endogenous flora: anaerobic, aerobic, or both
    - *E. coli*, *Staphylococcus*, *Streptococcus*, *Enterococcus*, *Bacteroides*, *Peptostreptococcus*, *H. influenzae*, *G. vaginalis*
    - cause of recurrent PID
    - associated with instrumentation
  - *Actinomyces israelii* (Gram-positive, non-acid-fast anaerobe)
    - 1-4% of PID cases associated with IUDs
  - others (TB, Gram-negatives, CMV, *U. urealyticum*, etc.)

Risk Factors
- age <30 yr
- risk factors as for chlamydia and gonorrhea
- vaginal douching
- IUD (within first 10 d after insertion)
- invasive gynecologic procedures (D&C, endometrial biopsy)

Clinical Feature
- up to 2/3 asymptomatic: many subtle or mild symptoms
- common: fever >38.3°C, lower abdominal pain and tenderness, abnormal discharge (cervical or vaginal)
- uncommon: N/V, dysuria, AUB
- chronic disease (often due to chlamydia)
  - constant pelvic pain
  - dyspareunia
  - palpable mass
  - very difficult to treat, may require surgery

Investigations
- blood work
  - β-hCG (must rule out ectopic pregnancy), CBC, blood cultures if suspect septicemia
- urine R&M
- speculum exam, bimanual exam
  - vaginal swab for Gram stain, C&S
  - cervical cultures for *N. gonorrhoeae*, *C. trachomatis*
  - endometrial biopsy will give definitive diagnosis (rarely done)
- ultrasound
  - may be normal
  - free fluid in cul-de-sac
  - pelvic or tubo-ovarian abscess
  - hydrosalpinx (dilated fallopian tube)
- laparoscopy (gold standard)
  - for definitive diagnosis: may miss subtle inflammation of tubes or endometritis
Treatment
- must treat with polymicrobial coverage

</tbody>
</table>

Complications of Untreated PID
- chronic pelvic pain
- abscess, peritonitis
- adhesion formation
- ectopic pregnancy
- infertility
  - 1 episode of PID: 13% infertility
  - 2 episodes of PID: 36% infertility
- bacteremia
- septic arthritis, endocarditis

Figure 15. Approach to pelvic pain
Toxic Shock Syndrome

- see Infectious Diseases, ID21

Risk Factors
- tampon use
- diaphragm, cervical cap, or sponge use (prolonged use, i.e. >24 h)
- wound infections
- post-partum infections
- early recognition and treatment of syndrome is imperative as incorrect diagnosis can be fatal

Clinical Feature
- sudden high fever
- sore throat, headache, diarrhea
- erythroderma
- signs of multisystem organ failure
- refractory hypotension
- exfoliation of palmar and plantar surfaces of the hands and feet 1-2 wk after onset of illness

Treatment
- remove potential sources of infection (foreign objects and wound debris)
- debride necrotic tissues
- adequate hydration
- penicillinase-resistant antibiotics (e.g. cloxacillin)
- steroid use controversial, but, if started within 72 h, may reduce severity of symptoms and duration of fever

Surgical Infections

Post-Operative Infections in Gynecological Surgery
- pelvic cellulitis
  - common post hysterectomy, affects vaginal vault
  - erythema, induration, tenderness, discharge involving vaginal cuff
  - treat if fever and leukocytosis with broad-spectrum antibiotics (i.e. clindamycin and gentamicin)
  - drain if excessive purulence or large mass
  - can result in intra-abdominal and pelvic abscess
- see General Surgery, Post-Operative Fever, GS7

Sexual Abuse
- see Family Medicine, FM26, Emergency Medicine, ER27

Sexuality and Sexual Dysfunction

SEXUAL RESPONSE
1. desire: energy that allows an individual to initiate or respond to sexual stimulation
2. arousal: physical and emotional stimulation leading to breast and genital vasodilation and clitoral engorgement
3. orgasm: physical and emotional stimulation is maximized, allowing the individual to relinquish their sense of control
4. resolution: most of the congestion and tension resolves within seconds, complete resolution may take up to 60 min

SEXUAL DYSFUNCTION

Etiology
- psychological or emotional: depression, abuse
- hormonal: menopause
- neurologic dysfunction: spinal cord injury
- vascular insufficiency: DM
- drug side effects: β-blockers
- trauma: episiotomy

Classification
- lack of desire (60-70% of women)
- lack of arousal
- anorgasmia (5-10%)
  - primary anorgasmia: never before achieved orgasm under any circumstances
  - secondary anorgasmia: was able to achieve orgasms before but now unable to
Menopause

- dyspareunia (3-6%): painful intercourse, superficial or deep
  - vaginismus (15%)
  - vulvodynia
  - vaginal atrophy
  - vulvar vestibulitis: associated with history of frequent yeast infections
  - PID

Treatment
- lack of desire: assess factors, rule out organic causes, relationship therapy, sensate focus exercises
- anorgasmia: self-exploration/pleasuring, relationship therapy if needed, bridging techniques (different sexual positions, clitoral stimulation during intercourse)
- dyspareunia
  - Kegel and reverse Kegel exercises
  - dilator treatment
  - comfort with self-exam
  - psychotherapy, other behavioural techniques
  - female on top position: allows for control of speed and duration
  - vestibulitis: remove local irritants, change in contraceptive methods, dietary changes (increased citrate, decreased oxalate), and vestibulectomy (rare)
  - vulvodynia: local moisturization, cold compresses, systemic nerve-blocking therapy (amitriptyline, gabapentin) orally or topically, topical anesthetics, estrogen cream
  - pain clinic
  - removal of environmental factors: bubble baths, soaps, perfumes, sanitary pads with plastic lining

Menopause

- see Family Medicine, FM40

Definitions
- lack of menses for 1 yr
- types of menopause
  - physiological; average age 51 yr (follicular atresia)
  - primary ovarian insufficiency; before age 40 (autoimmune disorder, infection, Turner’s syndrome)
  - iatrogenic (surgical/radiation/chemotherapy)

Clinical Features
- associated with estrogen deficiency
  - vasomotor instability (tends to dissipate with time)
  - hot flushes/flashes, night sweats, sleep disturbances, formication, nausea, palpitations
  - urogenital atrophy involving vagina, urethra, bladder
  - dyspareunia, pruritus, vaginal dryness, bleeding, post-coital bleeding, urinary frequency, urgency, incontinence
  - inspection may reveal: thinning of tissues, erythema, petechiae, bleeding points, dryness on speculum exam
  - skeletal
    - osteoporosis, joint and muscle pain, back pain
  - skin and soft tissue
    - decreased breast size, skin thinning/loss of elasticity
    - psychological
      - increased anxiety, depression, irritability, fatigue, decreased libido, memory loss

Investigations
- increased levels of FSH (>35 IU/L) on day 3 of cycle (if still cycling) and LH (FSH>LH)
- FSH level not always predictive due to monthly variation; use absence of menses for 1 yr to diagnose
- decreased levels of estradiol (later)

<tr>
<td>Transdermal</td>
<td>Estroderm®-Estradiol 0.05 mg/d or 0.1 mg/d</td>
<td>Estroderm®-MPA 2.5 mg PO OD</td>
<td>Use patch twice weekly Can use oral progestins (Estroderm®) Combined patches available (Estalis®)</td>
</tr>
<tr>
<td>Topical</td>
<td>Estrace® 2-4 g/d</td>
<td>Crinone® 4% or 8% (45 or 90 mg applicator)</td>
<td>If simultaneously taking oral estrogen tablet, may need to adjust dosing If intact uterus, also take progesterone</td>
</tr>
</tbody>
</table>

CEE = conjugated equine estrogen (e.g. Premarin®); MPA = medroxyprogesterone acetate (e.g. Provera®); NEA = norethindrone acetate
Consider lower dose regimens, PREMPRO® 0.45/1.5 (Premarin® 0.45 mg and Provera® 1.5 mg); Estrace® (topical 1%)-estradiol - 0.1 mg active ingredient/g; Premarin® (topical CEE) - 0.625 mg active ingredient/g; Estragon® (topical estrone) - 1 mg active ingredient/g

*Hormone Replacement Therapy

- see Family Medicine, FM40
- primary indication is treatment of menopausal symptoms (vasomotor instability)
- keep doses low (e.g. 0.3 mg Premarin®) and duration of treatment short (<5 yr)

HRT Components

- estrogen
- oral or transdermal (e.g. patch, gel)
- transdermal preferred for women overall, especially with hypertriglyceridemia or impaired hepatic function, smokers, and women who suffer from headaches associated with oral HRT
- low-dose (preferred dose: 0.3 mg Premarin®/25 µg Estradot® patch, can increase if necessary)
- progestin
- given in combination with estrogen for women with an intact uterus to prevent development of endometrial hyperplasia/cancer

Figure 18. Menopause pathophysiology

- Osteoporosis is the single most important health hazard associated with menopause
- Cardiovascular disease is the leading cause of death post-menopause
- Increased risk of breast cancer (RR 1.3) is associated with estrogen+progesterone HRT, but not with estrogen-only HRT
- All women taking HRT should have periodic surveillance and counselling regarding its benefits and risks

Figure 18. Menopause pathophysiology

- Degenerating theca cells fail to react to endogenous gonadotropins (FSH, LH)
- Less estrogen is produced
- Decreased negative feedback on hypothalamic-pituitary-adrenal axis
- Increased FSH and LH
- Stromal cells continue to produce androgens as a result of increased LH stimulation

Side Effects of HRT
- abnormal uterine bleeding
- mastodynia: breast tenderness and swelling
- edema, bloating, heartburn, nausea
- mood changes (progesterone)
- can be worse in progesterone phase of combined therapy

Contraindications to HRT
- absolute
  - acute liver disease
  - undiagnosed vaginal bleeding
  - history of breast cancer
  - known or suspected uterine cancer/breast cancer
  - acute vascular thrombosis or history of severe thrombophlebitis or thromboembolic disease
  - cardiovascular disease
- relative
  - pre-existing uncontrolled HTN
  - uterine fibroids and endometriosis
  - familial hyperlipidemias
  - migraine headaches
  - family history of estrogen-dependent cancer
  - chronic thrombophlebitis
  - DM (with vascular disease)
  - gallbladder disease, hypertriglyceridemia, impaired liver function (consider transdermal estrogen)
  - fibrocystic disease of the breasts

WOMEN’S HEALTH INITIATIVE (launched in 1991)
- two non-randomized studies investigating health risks and benefits of HRT in healthy postmenopausal women 50-79 yr old
  - continuous combined HRT (CEE 0.625 mg + MPA 2.5 mg OD) in 16,608 women with an intact uterus
  - estrogen-alone (CEE 0.625 mg) in 10,739 women with a previous hysterectomy
- both arms of the trial were stopped early because of evidence of increased risk of breast cancer, stroke, PE, and CHD in the combined HRT arm, and increased risk of stroke with no CHD benefits in the estrogen-alone arm
- the apparent increase in CHD was in disagreement with results of previous observational trial
- results of the WHI study have since been challenged and revision of how CHD was diagnosed led to loss of statistical significance of the results
- benefits and risks reported as number of cases per 10,000 women each year

Table 19. HRT Benefits vs. Risks

<table>
<thead>
<tr>
<th>Benefits</th>
<th>Risks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vasomotor Symptoms: less frequent and severe with use of either combined or estrogen alone HRT</td>
<td>Stroke: 8 additional cases with combined HRT and 12 additional cases for estrogen alone (WHI)</td>
</tr>
<tr>
<td>Osteoporosis: 5 fewer cases of hip fractures and 47 fewer cases of all fractures with combined HRT; 6 fewer cases of hip fractures with estrogen alone</td>
<td>DVT/PE: 18 additional cases with combined HRT and 9 additional cases for estrogen alone (WHI)</td>
</tr>
<tr>
<td>Colon Cancer: 6 fewer cases with combined HRT (WHI); one additional case with estrogen alone</td>
<td>CHD: 7 additional MIs with combined HRT (WHI); secondary analysis suggests greater absolute risk for women aged &gt;70 yr and for women who start HRT &gt;10 yr post-menopause</td>
</tr>
<tr>
<td></td>
<td>Breast Cancer: 8 additional cases with combined HRT (WHI); risk only increased after &gt;5 yr of combined HRT use; no increased risk for estrogen alone</td>
</tr>
<tr>
<td></td>
<td>Dementia and Mild Cognitive Impairment: 50% greater risk of developing dementia in women taking estrogen alone after age 65; risk is greater for women taking combined HRT, risk of developing dementia was reduced for women taking HRT before age 65</td>
</tr>
</tbody>
</table>
Pelvic Relaxation/Prolapse

Protrusion of pelvic organs into or out of the vagina

Grading of Pelvic Organ Prolapse

• 0 = no descent during straining
• 1 = distal portion of prolapse >1 cm above level of hymen
• 2 = distal portion of prolapse ≤1 cm above or below level of hymen
• 3 = distal portion of prolapse >1 cm below level of hymen but without complete vaginal eversion
• 4 = complete eversion of total length of lower genital tract

Procidentia: failure of genital supports and complete protrusion of uterus through the vagina

Etiology

• relaxation, weakness, or defect in the cardinal and uterosacral ligaments which normally maintain the uterus in an ante/retroflexed position and prevent it from descending through the urogenital diaphragm (i.e. levator ani muscles)
• related to:
  ■ vaginal childbirth
  ■ aging
  ■ decreased estrogen (post-menopause)
  ■ following pelvic surgery
  ■ increased intra-abdominal pressure (obesity, chronic cough, constipation, ascites, heavy lifting)
  ■ congenital (rarely)
  ■ ethnicity (Caucasian women > Asian or African women)
  ■ collagen disorders

General Conservative Treatment

(for pelvic relaxation/prolapse and urinary incontinence)

• Kegel exercises
• local vaginal estrogen therapy
• vaginal pessary (intravaginal suspension disc)
Table 20. Pelvic Prolapse

</tbody>
</table>

The only true hernia of the pelvis is an **ENTEROCELE** because peritoneum herniates with the small bowel.

---

**Urinary Incontinence**

- see Urology, U6

**STRESS INCONTINENCE**

**Definition**

- involuntary loss of urine with increased intra-abdominal pressure (cough, laugh, sneeze, walk, run)

**RISK FACTORS FOR STRESS INCONTINENCE IN WOMEN**

- age
- obesity
- parity
- vaginal delivery
- pelvic prolapse
- pelvic surgery
- hypoestrogenic state (post-menopause)
- smoking
- neurological/pulmonary disease

**Treatment**

- see Prolapse, GY36
- surgical
  - tension-free vaginal tape (TVT), tension-free obturator tape (TOT), prosthetic/fascial slings or retropubic bladder suspension (Burch or Marshall-Marchetti-Krantz procedures)

**URGE INCONTINENCE**

**Definition**

- urine loss associated with an abrupt, sudden urge to void
- "overactive bladder"
- diagnosed based on symptoms

**Etiology**

- idiopathic (90%)
- detrusor muscle overactivity ("detrusor instability")

**Associated Symptoms**

- frequency, urgency, nocturia, leakage

**Treatment**

- behaviour modification (reduce caffeine/liquid, smoking cessation, regular voiding schedule)
- Kegel exercises
- medications
  - anticholinergics: oxybutinin (Ditropan®), tolterodine (Detrol®), solifenacin (VESIcare®)
  - tricyclic antidepressants: imipramine

---

**Rule Out Neurological Causes of Urge Incontinence**

- MS
- Herniated disc
- DM
Pelvic Mass

**Gynecological Oncology**

**Pelvic Mass**

- **Ovarian**
  - Corpus luteum cyst
  - Follicular cyst
  - Theca lutein cyst
  - Hemorrhagic cyst

- **Neoplasm**
  - Benign
    - Dermoid cyst
    - Endometrioma
    - Epithelial cell
      - (most common in >40 yr)
      - Germ cell
      - (most common in <20 yr)
  - PCOS Tubo-ovarian abscess
  - Luteoma of pregnancy

    - Endometrial cancer
  - Asymmetrical
    - Leiomyoma
    - Leiomyosarcoma

- **Other**
  - Gynecological
    - Abdominal pregnancy
    - Pelvic adhesions (causing peritoneal inclusion cysts)
    - Pelvic adhesions (resulting in fluid entrapment)
  - Gastrointestinal
    - Appendiceal abscess
    - Diverticular abscess
    - Diverticulitis, diverticulosis
    - Carcinoma of rectum/colon
  - Genitourinary
    - Distended bladder
    - Pelvic kidney
    - Carcinoma of bladder
    - Imperforated hymen (causing hematocolpos)
    - Lymphoma

**Figure 20. Differential diagnosis of pelvic mass**

**Uterus**

**ENDOMETRIAL CARCINOMA**

**Epidemiology**
- most common gynecological malignancy in North America (40%); 4th most common cancer in women
- 2-3% of women develop endometrial carcinoma during lifetime
- mean age is 60 yr
- majority are diagnosed in early stage due to detection of symptoms
- 85-90% 5 yr survival for stage I disease
- 70-80% 5 yr survival for all stages

**Table 21. Features of Type I and Type II Endometrial Cancer**

<table>
<thead>
<tr>
<th>Type I Description (Both types related to estrogen, but Type II to a lesser degree)</th>
<th>Type II Description (Characterized as non-estrogen related: Non-endometrioid)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Characterized as estrogen-related (i.e. excess/unopposed estrogen): Endometrioid Includes well-differentiated endometrioid adenocarcinoma</td>
<td>Non-endometrioid Includes serous, clear cell, grade 4 endometrioid and undifferenitiated carcinomas, as well as carcinosarcoma More aggressive histologic subtypes; prognosis typically worse than type I, with a poorer 5 yr survival</td>
</tr>
</tbody>
</table>

**Risk Factors**
- Increasing age and family history are risk factors for both types
- PCOS
- Diabetes mellitus
- Unbalanced HRT (balanced HRT is protective)
- Nulliparity
- Late menopause (>35 yr), early menarche
- Estrogen-producing ovarian tumours (e.g. granulosa cell tumours)
- HNPCC (hereditary non-polyposis colorectal cancer)/Lynch II syndrome
- Tamoxifen
- Parous women
- Increasing age of menarche and number of children not significantly associated with reduced risk in clear-cell endometrial carcinoma
- Has been associated with p53 mutations

**Clinical Features**
- ~80% of cases
  - Postmenopausal bleeding in majority
  - Abnormal uterine bleeding in majority of affected pre-menopausal women
  - (menorrhagia, intermenstrual bleeding)
- ~15% of cases
  - Post-menstrual bleeding
  - Abnormal uterine bleeding
Screening
- no known benefit for mass screening
- annual endometrial sampling starting at age 30-35 only for women at high risk (HNPCC [Hereditary Non-Polyposis Colorectal Cancer] / Lynch II syndrome)
- routine pelvic ultrasound should not be used as screening test (high false positives)

Investigations
- endometrial sampling
  - office endometrial biopsy
  - D&C ± hysteroscopy
- ± pelvic ultrasound (in women where adequate endometrial sampling not feasible without invasive methods)
  - not acceptable as alternative to pelvic exam or endometrial sampling to rule out cancer

</tr>
</thead>
<tbody>
<tr>
<td>PURE TYPE</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1. Leiomyosarcoma</td>
<td>Most common type of uterine sarcoma</td>
<td>Histologic distinction from leiomyoma: 1. Increased mitotic count (&gt;10 mitoses/10 high-power fields) 2. Tumour necrosis 3. Cellular atypia</td>
<td>Often post-operatively after uterus removed for presumed fibroids</td>
<td>Hysterectomy/BSO usually No routine pelvic lymphadenectomy Chemotherapy is used in cases of metastatic disease Radiation therapy does not improve local control or survival Poor outcomes overall, even for early-stage disease</td>
</tr>
<tr>
<td>2. Endometrial Stromal Sarcoma (ESS)</td>
<td>Usually presents in perimenopausal or postmenopausal women with abnormal uterine bleeding</td>
<td>Abnormal uterine bleeding Good prognosis</td>
<td>Diagnosed by histology of endometrial biopsy or D&amp;C Stage using FIGO 2009 staging for leiomyosarcomas and ECC</td>
<td>Hysterectomy &amp; BSO (remove ovaries as ovarian hormones may stimulate growth) No routine pelvic lymphadenectomy Adjuvant therapy based on stage and histologic features (hormones and/or radiation) Hormonal therapy (progestins) may be used for metastatic disease</td>
</tr>
<tr>
<td>3. Undifferentiated Sarcoma</td>
<td>Rare; less common than leiomyosarcoma, endometrial stromal sarcoma</td>
<td>Severe nuclear pleomorphism, high mitotic activity, tumour cell necrosis, and lack smooth muscle or endometrial stromal differentiation Poor prognosis</td>
<td>Often found incidentally post-operatively for abnormal bleeding</td>
<td>Treatment primarily surgical Radiation and/or chemotherapy for advanced diseased or unresectable disease</td>
</tr>
</tbody>

</tr>
</thead>
<tbody>
<tr>
<td>4. Adenosarcoma</td>
<td>The rarest of the uterine sarcoma Mixed tumour of low malignancy potential</td>
<td>Present with abnormal vaginal bleeding Polyoid mass in uterine cavity</td>
<td>Mixture of benign epithelium with malignant low-grade sarcoma</td>
<td>Treatment is surgical with hysterectomy and BSO</td>
</tr>
</tbody>
</table>
BENIGN OVARIAN TUMOURS
- see Table 25
- many are asymptomatic
- usually enlarge slowly, if at all
- may rupture or undergo torsion, causing pain
  - pain associated with torsion of an adnexal mass usually originates in the iliac fossa and radiates to the flank
  - peritoneal irritation may result from an infarcted tumour (rare)

MALIGNANT OVARIAN TUMOURS
- see Table 25

Epidemiology
- lifetime risk 1.4%
- in women >50 yr, more than 50% of ovarian tumours are malignant
- causes more deaths in North America than all other gynecologic malignancies combined
- 4th leading cause of cancer death in women
- 85% epithelial; 15% non-epithelial
- 10-15% of epithelial ovarian cancers are related to hereditary predisposition

Risk Factors (for epithelial ovarian cancers)
- early menarche and/or late menopause
- personal history of breast, colon, endometrial cancer
- family history of breast, colon, endometrial, ovarian cancer
- Lynch syndrome and BRCA mutations
- use of fertility drugs

Protective Factors (for epithelial ovarian cancers)
- OCP: likely due to ovulation suppression (significant reduction in risk even after 1 yr of use)
- pregnancy/breastfeeding

Prophylactic Measures
- salpingectomy (prophylactic)
- BSO (prophylactic hysterectomy or tubal ligation performed for this reason in high-risk women [i.e. BRCA mutation carriers])

Screening
- no effective method of mass screening
- routine CA-125 level measurements or U/S not recommended
- high false positive rates
- controversial in high-risk groups: transvaginal U/S and/or CA-125, starting age 30 (no consensus on interval)
- familial ovarian cancer (>1 first degree relative affected, BRCA-1 mutation)
- other cancers (e.g. endometrial, breast, colon)
- BRCA-1 or BRCA-2 mutation: recommendation is prophylactic bilateral oophorectomy after age 35 or when childbearing is completed

Clinical Features
- most women with epithelial ovarian cancer present with advanced stage disease as patients often asymptomatic until disseminated (symptoms with early-stage disease are vague and non-specific)
- when present, symptoms may include:
  - abdominal symptoms (nausea, bloating, pain, dyspepsia, anorexia, early satiety)
  - symptoms of mass effect
    - increased abdominal girth (from ascites or tumour itself)
    - urinary urgency and frequency
    - constipation
Low Malignant Potential (also called “Borderline”) Tumours
- a subcategory of epithelial ovarian cancer (~15% of all epithelial ovarian tumours)
- pregnancy, OCP, and breastfeeding are protective factors
- tumour cells with histologically malignant characteristics arise from the ovarian surface, but do not invade ovarian stroma
- able to metastasise, but not commonly
- treated primarily with surgery (BSO/omental biopsy ± hysterectomy)
  - chemotherapy has limited benefit: can be treated with hormonal manipulation (letrozole)
- generally slow growing, excellent prognosis
  - 5 yr survival >99%
  - recurrences tend to occur late, may be associated with low-grade serous carcinoma

*FIGO = International Federation of Gynecology and Obstetrics*
Fallopian Tube

- least common site for carcinoma of female reproductive system (0.3%)
- usually serous epithelial carcinoma
- new evidence shows that some serous ovarian cancers originate in the fallopian tube
- more common in fifth and sixth decade

Clinical Features
- classic triad present in minority of cases, but very specific
  - watery discharge (most specific): “hydrops tubae profunda”
  - vaginal bleeding or discharge in 50% of patients
  - crampy lower abdominal/pelvic pain
  - most patients present with a pelvic mass (see Ovarian Tumours, GY41 for guidelines regarding diagnosis/investigation)

Treatment
- as for malignant epithelial ovarian tumours

Cervix

BENIGN CERVICAL LESIONS
- Nabothian cyst/inclusion cyst: no treatment required
- endocervical polyps: treatment is polypectomy (office procedure)

MALIGNANT CERVICAL LESIONS

Epidemiology
- majority are SCC (95%); adenocarcinomas increasing (5%); rare subtypes include small cell, adenosquamous
- 8000 deaths annually in North America
- annual Pap test reduces a woman’s chance of dying from cervical cancer from 0.4% to 0.05%
- average age at presentation: 52 yr old

Etiology
- at birth, vagina is lined with squamous epithelium; columnar epithelium lines only the endocervix and the central area of the ectocervix (original squamocolumnar junction)
- during puberty, estrogen stimulates eversion of a single columnar layer (ectopy), thus exposing it to the acidic pH of the vagina, leading to metaplasia (change of exposed epithelium from columnar to squamous)
- a new squamocolumnar junction forms as a result
- the transformation zone (TZ) is the area located between the original and the current squamocolumnar junction
- the majority of dysplasias and cancers arise in the TZ of the cervix
- must have active metaplasia in presence of inducing agent (HPV) to get dysplasia
- dysplasia progresses to carcinoma in situ (CIS), which further progresses to invasion
- slow process (~10 yr on average)
- growth is by local extension
- metastasis occurs late

Risk Factors
- HPV infection
  - see Sexually Transmitted Infections, GY26
  - high risk of neoplasia associated with types 16, 18
  - low risk of neoplasia associated with types 6, 11
  - >99% of cervical cancers contain one of the high risk HPV types
- high-risk behaviours (risk factors for HPV infection)
  - multiple partners
  - other STIs (HSV, trichomonas)
  - early age at first intercourse
  - high-risk male partner
  - smoking
- poor screening uptake is the most important risk factor for cervical cancer in Canada
- at-risk groups include:
  - immigrant Canadians
  - First Nations Canadians
  - geographically-isolated Canadians
  - sex-trade workers
  - low socioeconomic status Canadians

Cervical Cancer Screening Guidelines (Pap Test)
- see Family Medicine, FM5
Clinical Features
- SCC: exophytic, fungating tumour
- adenocarcinoma: endophytic, with barrel-shaped cervix
- early
  - asymptomatic
  - discharge: initially watery, becoming brown or red
  - postcoital bleeding
- late
  - 80-90% present with bleeding; either postcoital, postmenopausal or irregular bleeding
  - pelvic or back pain (extension of tumour to pelvic walls)
  - bladder/bowel symptoms
- signs
  - friable, raised, reddened, or ulcerated area visible on cervix

Figure 22. Decision making chart for Pap test (not applicable for adolescents)
Adapted from: Ontario Cervical Screening Practice Guidelines. May 2012. Cervical screening guidelines unique to each province

Diagnosis
- colposcopy is a clinical procedure that facilitates identification and biopsy of suspicious cells
- in colposcopy:
  - apply acetic acid and identify acetowhite lesions, punctuation, mosaicism, and abnormal blood vessels to guide cervical biopsy
  - endocervical curettage (ECC) if entire lesion is not visible or no lesion visible
  - diagnostic excision (LEEP) if:
    - unsatisfactory colposcopy (poor visualization/access to transformation zone)
    - discrepancy between cytology, colposcopy, and histological findings
    - positive findings/glandular abnormalities in endocervical curettage
    - suspicious for adenocarcinoma in situ (consider cold-knife conization)
    - recurrence of lesion post-ablation or excision
    - inability to rule out invasive disease, i.e. large lesions (lesions extending into endocervical canal, extending widely on cervix, or onto vaginal epithelium)
- consider cold-knife conization (in OR) if glandular abnormality suspected based on cytology or colposcopic findings due to concern for margin interpretation
- tests permitted for FIGO clinical staging include: physical exam (including examination under anesthesia), cervical biopsy (including cone biopsy), proctoscopy/cystoscopy, intravenous pyelogram, ultrasound liver/kidneys, CXR, LFTs
- MRI and/or CT and/or PET scan often done to facilitate planning of radiation therapy; results do not influence clinical stage

*Gardasil-9 also covers types 31, 33, 45, 52, and 58; also used to prevent genital warts

- should be administered before onset of sexual activity (i.e. before exposure to virus) for optimal benefit of vaccination
- may be given at the same time as hepatitis B or other vaccines using a different injection site
- not for treatment of active infections
- most women will not be infected with all four types of the virus at the same time, therefore vaccine is still indicated for sexually active females or those with a history of previous HPV infection or HPV-related disease
- conception should be avoided until 30 d after last dose of vaccination

Causes of Elevated CA-125

- Age influences reliability of test as a tumour marker
- 50% sensitivity in early stage ovarian cancer (poor) – therefore not good for screening

Malignant

- Gynec: ovary, uterus
- Non-Gynec: pancreas, stomach, colon, rectum

Non-Malignant

- Gynec: benign ovarian neoplasm, endometriosis, pregnancy, fibroids, PID
- Non-Gynec: cirrhosis, pancreatitis, renal failure

Cervical Cancer Prognosis 5 yr Survival

- Stage 0: 99%
- Stage I: 75%
- Stage II: 55%
- Stage III: 30%
- Stage IV: 7%
- Overall: 50-60%

Efficacy of Human Papillomavirus (HPV)-16/18 AS04-Adjuvanted Vaccine Against Cervical Infection and Precancer Caused by Oncogenic HPV Types (PATRICIA): Final Analysis of a Double-Blind, Randomized Study in Young Women

- Lancet 2009;374:301-14
- Study: Phase III double-blind, controlled RCT
- Patients: 18,644 women aged 15-25
- Selected Outcomes: Development of HPV-16/18 associated CIN II+ was the primary outcome. Secondary to this were persistence of infections with HPV-16, HPV-18, or other oncogenic HPV types.
- Selected Results: Efficacy against development of HPV-16/18 associated CIN II+ was 98.1% (p<0.0001). High levels of cross-protection were observed for persistent infection with HPV-31 and HPV-45 and HPV-31 or HPV-45 associated CIN II.
- Conclusions: The HPV-16/18 AS04-adjuvanted vaccine protected against HPV-16/18 associated CIN II+ – lesions and lesions associated with HPV-31, HPV-33, and HPV-45.

</tr>
</tbody>
</table>

**Stage IA1 (no LVSII)**
- LEEP if future fertility desired (and lesion ≤2 cm)
- Simple hysterectomy if future fertility is not desired

**Stage IA2, IB1**
- Typically treated with radical hysterectomy and pelvic lymphadenectomy (sentinel nodes under study)
- If high chance of adjuvant radiation then consider primary chemoradiation as more morbidity occurs from double-modality treatment (surgery and radiation)
- Equal cure rates may be obtained with primary radiation therapy; advantage of surgery: may accurately stage and grade and more targeted adjuvant therapy
- Advantage is that ovaries can be spared if pre-menopausal
- For fertility preservation (if tumour <2 cm), may have radical trachelectomy (removal of cervix and parametria) and nodes instead of radical hysterectomy for early-stage disease
- Chemoradiation therapy if adverse high-risk prognostic factors on radical surgical specimen, such as: positive pelvic lymph nodes, positive parametria, and/or positive margins or adverse cervical factors (2 or more): deep stromal invasion, size >4 cm, LVSII

**Stages IB2 (>4 cm), II, III, IV**
- Primary chemoradiation therapy
- CT assess extent of disease: evaluate pelvic and para-aortic nodes
- For positive nodes on PET: primary chemoradiation with extended field RT
- Hysterectomy generally not suggested following primary treatment with curative intent

Abnormal Pap Tests in Pregnancy
- incidence: 1/2200
- Pap test at all initial prenatal visits
  - if abnormal Pap or suspicious lesion, refer to colposcopy
  - if diagnostic conization required, should be deferred until second trimester (T2) to minimize risk of pregnancy loss
  - if invasive cancer ruled out, management of dysplasia deferred until completion of pregnancy (may deliver vaginally)
  - if invasive cancer present, management depends on prognostic factors, degree of fetal maturity, and patient wishes
    - general recommendations in T1: consider pregnancy termination, management with either radical surgery (hysterectomy vs. trachelectomy if desires future fertility), or concurrent chemoradiation therapy
    - recommendations in T2/T3: delay of therapy until viable fetus and C-section for delivery with concurrent radical surgery or subsequent concurrent chemoradiation therapy

Vulva

BENIGN VULVAR LESIONS

Non-Neoplastic Disorders of Vulvar Epithelium
- biopsy is necessary to make diagnosis and/or rule out malignancy:
  1) Hyperplastic dystrophy (squamous cell hyperplasia)
    - surface thickened and hyperkeratotic
    - pruritus most common symptom
    - typically postmenopausal women
    - treatment: 1% fluorinated corticosteroid ointment bid for 6 wk
  2) Lichen sclerosis
    - subepithelial fat becomes diminished; labia become thin, atrophic, with membrane-like epithelium and labial fusion
    - pruritus, dyspareunia, burning
    - figure of 8’ distribution
    - most common in postmenopausal women but can occur at any age
    - treatment: ultrapotent topical steroid 0.05% clobetasol x 2–4 wk then taper down, can consider long-term suppression twice a week
  3) Mixed dystrophy (lichen sclerosis with epithelial hyperplasia)
    - hyperkeratotic areas with areas of thin, shiny epithelium
    - treatment: fluorinated corticosteroid ointment
Tumours
- papillary hidradenoma, nevus, fibroma, hemangioma

MALIGNANT VULVAR LESIONS

Epidemiology
- 5% of genital tract malignancies
- 90% SCC; remainder melanomas, basal cell carcinoma, Paget’s disease, Bartholin’s gland carcinoma
  - Type I disease: HPV-related (50-70%)
    - more likely in younger women
    - 90% of vulvar intraepithelial neoplasia (VIN) contain HPV DNA (usually types 16, 18)
  - Type II disease: not HPV-related, associated with current or previous vulvar dystrophy
    - usually postmenopausal women

Risk Factors
- HPV infection
  - VIN: precancerous change which presents as multicentric white or pigmented plaques on vulva (may only be visible at colposcopy)
    - progression to cancer rarely occurs with appropriate management
    - treatment: local excision (i.e. superficial vulvectomy ± split thickness skin grafting to cover defects if required) vs. ablative therapy (i.e. laser, cauterization) vs. local immunotherapy (imiquimod)
- history of cervical cancer
- cigarette smoking
- immunodeficiency

Clinical Features
- many patients asymptomatic at diagnosis (many also deny or minimize symptoms)
- most lesions occur on the labia majora, followed by the labia minora (less commonly on the clitoris or perineum)
- localized pruritus or lesion most common
- less common: raised red, white or pigmented plaque, ulcer, bleeding, discharge, pain, dysuria
- patterns of spread
  - local
  - groin lymph nodes (usually inguinal, then spreading to pelvic nodes)
  - hematogenous

Investigations
- ± vulvar biopsy
- always biopsy any suspicious lesion
  - do not remove entire lesion (allows for site identification through sentinel LN injection if malignant)

Prognosis
- depends on stage: particularly nodal involvement (single most important predictor followed by tumour size)
- lesions >4 cm associated with poorer prognosis
- overall 5 yr survival rate: 79%

Treatment
- T1 lesions (tumour confined to vulva; no extension to adjacent perineal structures): radical local excision
- T2 lesions (tumour of any size with extension to adjacent perineal structures): modified radical vulvectomy
- T3 lesions (extension to any of: proximal 2/3 of urethra, proximal 2/3 of the vagina, bladder mucosa, rectal mucosa, or fixed to pelvic bone): chemoradiation followed by selective resection of residual primary
- node positive disease: adjuvant chemoradiation or radiation therapy

Any suspicious lesion of the vulva should be biopsied
Vagina

BENIGN VAGINAL LESIONS

- inclusion cysts
  - cysts form at site of abnormal healing of laceration (e.g. episiotomy)
  - no treatment required
- endometriosis
  - dark lesions that tend to bleed at time of menses
  - treatment: excision
- Gartner's duct cysts
  - remnants of Wolffian duct, seen along side of cervix
  - treatment: conservative unless symptomatic
- urethral diverticulum
  - can lead to recurrent urethral infection, dyspareunia
  - treatment: surgical correction if symptomatic

MALIGNANT VAGINAL LESIONS

Epidemiology

- primary carcinomas of the vagina represent 2-3% of malignant neoplasms of the female genital tract
- 80-90% are SCC
- more than 50% diagnosed between 70-90 yr old

Risk Factors

- associated with HPV infection (analogous to cervical cancer)
- increased incidence in patients with prior history of cervical and vulvar cancer

Investigations

- cytology
  - significant false negative rate for existing malignancy (i.e. if gross lesion present, biopsy)
- colposcopy
- Schiller test (normal squamous epithelium takes up Lugol's iodine)
- biopsy, partial vaginectomy (wide local excision for diagnosis)
- rule out disease on cervix, vulva, or anus (most vaginal cancers are metastatic from one of these sites)
- staging

Clinical Features

Table 30. Clinical Features of Malignant Vaginal Lesions

<tr>
<td></td>
<td>2 types: non-DES and DES syndrome</td>
</tr>
</tbody>
</table>

Treatment

- Stage I
  - radiation therapy: for tumours >2 cm diameter or tumour involvement of the mid- to low-grade vagina
  - surgical excision: radical hysterectomy, upper vaginectomy, and bilateral pelvic lymphadenectomy
- Stage II-IV: chemoradiation
Gestational Trophoblastic Disease/Neoplasia

- refers to a spectrum of proliferative abnormalities of the trophoblast

**Epidemiology**
- 1/1000 pregnancies
- marked geographic variation (as high as 1/125 in Taiwan)
- 80% benign, 15% locally invasive, 5% metastatic
- cure rate >95%

**HYDATIDIFORM MOLE (Benign GTD)**

**Complete Mole**
- most common type of hydatidiform mole
- diffuse trophoblastic hyperplasia, hydropic swelling of chorionic villi, no fetal tissues or membranes present
- 46XX or 46XY, chromosomes completely of paternal origin (90%)
- 2 sperm fertilize empty egg or 1 sperm with reduplication
- 15-20% risk of progression to malignant sequelae
- risk factors
  - geographic (South East Asia most common)
  - others (maternal age >40 yr, β-carotene deficiency, vitamin A deficiency not proven)
- clinical features often present during apparent pregnancy with abnormal symptoms/findings
  - vaginal bleeding (97%)
  - hyperemesis gravidarum (26%)
  - excessive uterine size for LMP (51%)
  - hyperthyroidism (7%)
  - theca-lutein cysts >6 cm (50%)
  - β-hCG >100,000 IU/L
  - preeclampsia (27%)
  - no fetal heartbeat detected

**Partial (or Incomplete) Mole**
- focal trophoblastic hyperplasia and hydropic villi are associated with fetus or fetal parts
- often triploid (XXY, XYY, XXX) with chromosome complement from both parents
- usually related to single ovum fertilized by two sperm
- low risk of progression to malignant sequelae (<4%)
- associated with fetus, which may be growth-restricted, and/or have multiple congenital malformations
- clinical features
  - typically present similar to threatened/spontaneous/missed abortion
  - pathological diagnosis often made after D&C

**Investigations**
- quantitative β-hCG levels (tumour marker) abnormally high for gestational age
- U/S findings
  - if complete: no fetus (classic “snow storm” due to swelling of villi)
  - if partial: molar degeneration of placenta ± fetal anomalies, multiple echogenic regions corresponding to hydropic villi, and focal intrauterine hemorrhage
- CXR (may show metastatic lesions)
- features of molar pregnancies at high risk of developing persistent GTN post-evacuation
  - local uterine invasion as high as 31%
  - β-hCG >100,000 IU/L
  - excessive uterine size
  - prominent theca-lutein cysts

**Treatment**
- suction D&C with sharp curettage and oxytocin
- Rhogam® if Rh negative
- prophylactic chemotherapy of no proven benefit
- chemotherapy for GTN if develops after evacuation

**Follow-up**
- contraception required to avoid pregnancy during entire follow-up period
- serial β-hCGs (as tumour marker) every week until negative x 3 (usually takes several wk), then monthly for 6-12 mo prior to trying to conceive again
- increase or plateau of β-hCG indicates GTN: patient needs chemotherapy

**GTN (MALIGNANT GTD)**

**Invasive Mole or Persistent GTN**
- diagnosis made by rising or plateau in β-hCG, development of metastases following treatment of documented molar pregnancy
- histology: molar tissue from D&C
- metastases are rare (4%)
Choriocarcinoma
- often present with symptoms from metastases
- highly anaplastic, highly vascular
- no chorionic villi, elements of syncytiotrophoblast and cytotrophoblast
- may follow molar pregnancy, abortion, ectopic, or normal pregnancy

Placental-Site Trophoblastic Tumour
- rare aggressive form of GTN
- abnormal growth of intermediate trophoblastic cells
- low β-hCG, production of human placental lactogen (hPL), relatively insensitive to chemotherapy

CLASSIFICATION of GTN
- non-metastatic
  - ~15% of patients after molar evacuation
  - may present with abnormal bleeding
  - all have rising or plateau of β-hCG
  - negative metastases on staging investigations
- metastatic
  - 4% of patients after treatment of complete molar pregnancy
  - metastasis more common with choriocarcinoma, which tends toward early vascular invasion and widespread dissemination
  - if signs or symptoms suggest hematogenous spread, do not biopsy (they bleed)
    - lungs (80%): cough, hemoptysis, CXR lesion(s)
    - vagina (30%): vaginal bleeding, “blue lesions” on speculum exam
    - pelvis (20%): rectal bleeding (if invades bowel), U/S lesion(s)
    - liver (10%): elevated LFTs, U/S or CT findings
    - brain (10%): headaches, dizziness, seizure (symptoms of space-occupying lesion), CT/MRI findings
  - highly vascular tumour, which is more likely to bleed and result in anemia
  - all have rising or plateau of β-hCG
  - classification of metastatic GTN
    - divided into good prognosis and bad prognosis
    - features of bad prognosis
      - long duration (>4 mo from antecedent pregnancy)
      - high pre-treatment β-hCG titre: >100,000 IU/24 h urine or >40,000 IU/L of blood
      - brain or liver metastases
      - prior chemotherapy
      - metastatic disease following term pregnancy
    - good prognosis characterized by the absence of each of these features

Investigations (for Staging)
- blood work: CBC, electrolytes, creatinine, β-hCG, TSH, LFTs
- imaging: CXR, U/S pelvis only
- if CXR shows lung metastasis then CT abdo/pelvis, MRI brain
- if suspect brain metastasis but CT brain negative, consider lumbar puncture for CSF β-hCG
- ratio of plasma β-hCG:CSF β-hCG <60 indicates metastases

Follow-up (for GTN)
- contraception for all stages to avoid pregnancy during entire follow-up period
- stage I, II, III
  - weekly β-hCG until 3 consecutive normal results
  - then monthly x 12 mo
- stage IV
  - weekly β-hCG until 3 consecutive normal results
  - then monthly x 24 mo

GTN Diagnosis
- β-hCG plateau: <10% drop in β-hCG over four values in 3 wk (e.g. days 1, 7, 14, and 21) OR
- β-hCG rise >20% in any two values over two wk or longer (e.g. measure at days 1, 7, 14) OR
- β-hCG persistently elevated >6 mo OR
- metastases on work-up

<td>Dopaminomimetic, agonist at D2R and antagonist at D1R; acts directly on anterior pituitary cells to inhibit synthesis and release of prolactin Initial: 1.25-2.5 mg PO qhs with food Then: increase by 1.25 mg every 2-7 d as needed until optimal therapeutic response Usual Range: 1.5-15 mg OD For IVF: Initial: 1.25 mg/d PO between days 4-6 of follicular phase Then: 2.5 mg/d until 3 d after onset menstruation</td>
<td>Galactorrhea + amenorrhea 2° to hyperprolactinemia Prolactin-dependent menstrual disorders and infertility Prolactin-secreting adenomas (microadenomas, prior to surgery of macroadenomas) IVF</td>
<td>S/E: N/V, headache, postural hypotension, somnolence C/I: uncontrolled HTN, pregnancy-induced HTN, CAD, breastfeeding D/I: domperidone, macrolides, octreotide</td>
<td></td>
</tr>
<tr>
<td>clomiphene citrate (Clomid®)</td>
<td>Increases output of pituitary gonadotropins to induce ovulation</td>
<td>50 mg OD x 5 d Try 100 mg or 160 mg OD If ineffective 3 courses: adequate trial</td>
<td>Patients with persistent ovulatory dysfunction (e.g. amenorrhea, PCOS) who desire pregnancy</td>
<td>S/E: Common: hot flashes, abdominal discomfort, exaggerated cyclic ovarian enlargement, accentuation of Mittelschmerz Rare: ovarian hyperstimulation syndrome, multiple pregnancy, visual blurring, birth defects C/I: pregnancy, liver disease, hormone-dependent tumours, ovarian cyst, undiagnosed vaginal bleeding</td>
</tr>
<tr>
<td>clotrimazole (Canesten®)</td>
<td>Antifungal; disrupt fungal cell membrane</td>
<td>Tablet: 100 mgbd intravaginally x 7 d or 200 mg x 3 d or 500 mg x 1 dose Cream: 1 or 2% 1 applicator intravaginally ghs x 3-7 d Topical: apply bid x 7 d</td>
<td>Vulvovaginal candidiasis</td>
<td>S/E: vulvar/vaginal burning</td>
</tr>
<tr>
<td>danazol (Cyclomen® CAN) (Danocrine® US)</td>
<td>Synthetic steroid: inhibits pituitary gonadotropin output and ovarian steroid synthesis Has mild androgenic properties</td>
<td>200-800 mg in 2-3 divided doses Use for 3-6 mo Biannual hepatic US required if &gt;6 mo use</td>
<td>Endometriosis 1° menorrhagia/DUB</td>
<td>S/E: weight gain, acne, mild hirsutism, hepatic dysfunction C/I: pregnancy, undiagnosed vaginal bleeding, breastfeeding, severely impaired renal/hepatic/cardiac function, porphyria, genital neoplasia, thromboembolic disease D/I: warfarin, carbamazepine, cyclosporine, tacrolimus, anti-hypertensives</td>
</tr>
</tbody>
</table>

</tr>
<tr>
<td>tranexamic acid (Cyklokapron®)</td>
<td>Anti-fibrinolytic; reversibly inhibits plasminogen activation</td>
<td>1-1.5 g tid-qid for first 4 d of cycle Max 4 g/d Ophthalmic check if used for several wk</td>
<td>Menorrhagia</td>
<td>S/E: N/V, diarrhea, dizziness, rare cases of thrombosis, abdominal pain, MSK pain C/I: thromboembolic disease, acquired disturbances of colour vision, subarachnoid hemorrhage, age &lt;15 yr</td>
</tr>
<tr>
<td>ulipristal acetate (Fibristal®)</td>
<td>Selective progesterone receptor modulator (SPRMI)</td>
<td>5 mg PO OD for max 3 mo; first tablet taken anytime during first 7 d of menstruation</td>
<td>Leiomyoma (pre-operative)</td>
<td>S/E: headache, hot flushes, constipation, vertigo, endometrial thickening C/I: pregnancy, undiagnosed vaginal bleeding, any gynecological cancer</td>
</tr>
<tr>
<td>urofollitropin (Metrodin®)</td>
<td>FSH</td>
<td>75 U/d SC x 7-12 d</td>
<td>Ovulation induction in PCOS</td>
<td>S/E: ovarian enlargement or cysts, edema and pain at injection site, arterial thromboembolism, fever, abdominal pain, headache, multiple pregnancy C/I: primary ovarian failure, intracranial lesion (e.g. pituitary tumour), uncontrolled thyroid/adrenal dysfunction, ovarian cyst (not PCOS), pregnancy, undiagnosed uterine bleeding</td>
</tr>
<tr>
<td>combined oral contraceptive pill (OCP)</td>
<td>Ovulatory suppression by inhibiting LH and FSH Decidualization of endometrium Thickening of cervical mucus to prevent sperm penetration</td>
<td></td>
<td>Contraception Disorders of menstruation</td>
<td>See Table 8-12</td>
</tr>
<tr>
<td>intrauterine device (IUD) copper IUD (Nova-T®)</td>
<td>Copper IUD: mild foreign body reaction in endometrium, which is toxic to sperm and alters sperm motility Progesterone-releasing IUD: decidualization of endometrium and thickening of cervical mucus, may suppress ovulation</td>
<td>Contraceptive effects last 3 yr (Jaydess®); up to 5 yr (Copper IUD, Mirena®)</td>
<td>Same as above</td>
<td>See Table 8-12</td>
</tr>
</tbody>
</table>
Figure 1. Hematopoiesis
Basics of Hematology

- over $10^{11}$ blood cells are produced daily
- sites of hematopoiesis in adults: pelvis, sternum, vertebral bodies, and cranium
- lifespan of mature cells in blood
  - erythrocytes (90-120 d), neutrophils (~1 d), platelets (7-10 d), lymphocytes (varies – memory cells persist for years)
- role of lymphoid organs
  - spleen: part of reticuloendothelial system, sequesters aged RBCs, removes opsonized cells, and site of antibody production
  - thymus: site of T-cell maturation and involutes with age
  - lymph nodes: sites of B and T-cell activation (adaptive immune response)

### Complete Blood Count

**Table 1. Common Terms Found in the CBC**

<table>
<thead>
<tr>
<th>Test</th>
<th>Definition</th>
<th>Normal Values*</th>
</tr>
</thead>
<tbody>
<tr>
<td>Red Blood Cell (RBC) Count</td>
<td>The number of RBCs per volume of blood</td>
<td>4.2-6.9 x 10^9/mm³</td>
</tr>
<tr>
<td>Hemoglobin (Hb)</td>
<td>Amount of oxygen-carrying protein in the blood</td>
<td>130-180 g/L (male) / 120-160 g/L (female)</td>
</tr>
<tr>
<td>Hematocrit (Hct)</td>
<td>Percentage of a given volume of whole blood occupied by packed RBCs</td>
<td>45%-62% (male) / 37%-48% (female)</td>
</tr>
<tr>
<td>Mean Corpuscular Volume (MCV)</td>
<td>Measurement of RBC size</td>
<td>80-100 µm³</td>
</tr>
<tr>
<td>Mean Corpuscular Hb (MCH)</td>
<td>Amount of oxygen-carrying Hb inside RBCs</td>
<td>27-32 pg/cell</td>
</tr>
<tr>
<td>Mean Corpuscular Hb Concentration (MCHC)</td>
<td>Average concentration of Hb inside RBCs</td>
<td>32%-36%</td>
</tr>
<tr>
<td>RBC Distribution Width (RDW)</td>
<td>Measurement of variance in RBC size</td>
<td>11.0%-15.0%</td>
</tr>
<tr>
<td>White Blood Cell (WBC) Count</td>
<td>The number of WBCs per volume of blood</td>
<td>4.3-10.8 x 10^9/mm³</td>
</tr>
<tr>
<td>WBC Differential</td>
<td></td>
<td></td>

</tr>
<tr>
<td>Monocytes</td>
<td></td>
<td>0.1-1.0 x 10^9/mm³</td>
</tr>
<tr>
<td>Eosinophils</td>
<td></td>
<td>0.0-0.4 x 10^9/mm³</td>
</tr>
<tr>
<td>Basophils</td>
<td></td>
<td>0.0-0.2 x 10^9/mm³</td>
</tr>
<tr>
<td>Platelet Count</td>
<td>The number of platelets per volume of blood</td>
<td>150-400 x 10^9/mm³</td>
</tr>
<tr>
<td>Mean Platelet Volume (MPV)</td>
<td>Measurement of platelet size</td>
<td>7.2-11.7 FL</td>
</tr>
<tr>
<td>Reticulocytes</td>
<td>Immature RBCs that contain no nucleus but have residual RNA</td>
<td>Normally make up 1% of total RBC count</td>
</tr>
</tbody>
</table>

*Normal values may vary depending on site and age

**Approach to Interpreting a CBC**

1. consider values in the context of individual's baseline:
   - up to 5% of population without disease may have values outside “normal” range
   - an individual may display a clinically significant change from their baseline without violating “normal” reference range
2. is one cell line affected or are several?
   - if all lines are low: pancytopenia (see Pancytopenia, H8)
   - if RBCs and platelets are low: consider a MAHA/TMA (see Microangiopathic Hemolytic Anemia/Thrombotic Microangiopathy, H22)
   - if single cell line affected: see Common Presenting Problems, H6

**Blood Film Interpretation**

**RED BLOOD CELLS**

**Size**
- microcytic (MCV <80 µm³), normocytic (MCV = 80-100 µm³), macrocytic (MCV >100 µm³)
- anisocytosis: RBCs with increased variability in size (increased RDW)
  - iron deficiency anemia, hemolytic anemias, myelofibrosis, blood transfusion, and MDS

**Colour**
- hypochromic: increase in size of central pallor (normal = less than 1/3 of RBC diameter)
  - iron deficiency anemia, anemia of chronic disease, and sideroblastic anemia
- polychromasia: increased reticulocytes (pinkish-blue cells)
  - increased RBC production by bone marrow

**Shape**
- poikilocytosis: increased proportion of RBCs of abnormal shape
  - iron deficiency anemia, myelofibrosis, severe B₁₂ deficiency, MDS, and burns
Table 2. Common Erythrocyte Shapes

<table>
<thead>
<tr>
<th>Shape</th>
<th>Definition</th>
<th>Associated Conditions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Discocyte</td>
<td>Biconcave disc</td>
<td>Normal RBC</td>
</tr>
<tr>
<td>Spherocyte</td>
<td>Spherical RBC (due to loss of membrane)</td>
<td>Hereditary spherocytosis, immune hemolytic anemia</td>
</tr>
<tr>
<td>Elliptocyte/Ovalocyte</td>
<td>Oval-shaped, elongated RBCs</td>
<td>Hereditary elliptocytosis, megaloblastic anemia, iron-deficiency, and MDS</td>
</tr>
<tr>
<td>Schistocyte (helmet cell, fragment)</td>
<td>Fragmented cells (due to traumatic disruption of membrane)</td>
<td>Microangiopathic hemolytic anemia (HUS, aHUS, TTP, DIC, preeclampsia, HELLP, malignant HTN, vasculitis, glomerulonephritis, and prosthetic heart valve)</td>
</tr>
<tr>
<td>Sickle Cell</td>
<td>Sickle-shaped RBC (due to polymerization of hemoglobin S)</td>
<td>Sickle cell disorders: HbSC, HbSS</td>
</tr>
<tr>
<td>Codocyte (target cell)</td>
<td>“Bull’s eye” on dried film</td>
<td>Liver disease, hemoglobin SC, thalassemia, iron deficiency, and asplenia</td>
</tr>
<tr>
<td>Dacrocyte (teardrop cell)</td>
<td>Single pointed end, looks like a teardrop</td>
<td>Myelofibrosis, MDS, thalassemia major, megaloblastic anemia, and bone marrow infiltration</td>
</tr>
<tr>
<td>Acanthocyte (spur cell)</td>
<td>Distorted RBC with irregularly distributed thorn-like projections (due to abnormal membrane lipids)</td>
<td>Severe liver disease (spur cell anemia), starvation/anorexia, and post-splenectomy</td>
</tr>
<tr>
<td>Echinocyte (burr cell)</td>
<td>RBC with numerous regularly spaced, small, spiny projections</td>
<td>Uremia, HUS, burns, cardiopulmonary bypass, post-transfusion, and storage artifact</td>
</tr>
<tr>
<td>Rouleaux Formation</td>
<td>Aggregates of RBC resembling stacks of coins (due to increased plasma concentration of high molecular weight proteins)</td>
<td>Pregnancy is most common cause (due to physiological increase in fibrinogen) Inflammatory conditions (due to polyclonal immunoglobulins) Plasma cell dyscrasias (due to monoclonal paraproteinemia, e.g. multiple myeloma, macroglobulinemia) Storage artifact</td>
</tr>
</tbody>
</table>

DIC = disseminated intravascular coagulation; HELLP = hemolysis, elevated liver enzymes, and low platelet count; HUS = hemolytic uremic syndrome; aHUS = atypical HUS; TTP = thrombotic thrombocytopenic purpura

Table 3. RBC Inclusions

<table>
<thead>
<tr>
<th>Inclusions</th>
<th>Definition</th>
<th>Associated Conditions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nucleus</td>
<td>Present in erythroblasts (immature RBCs)</td>
<td>Hyperplastic erythropoiesis (seen in hypoxia, hemolytic anemia), BM infiltration disorders, and MPNs (MF)</td>
</tr>
<tr>
<td>Heinz Bodies</td>
<td>Denatured and precipitated hemoglobin</td>
<td>G6PD deficiency (post-exposure to oxidant), thalassemia, and unstable hemoglobins</td>
</tr>
<tr>
<td>Howell-Jolly Bodies</td>
<td>Small nuclear remnant resembling a pyknotic nucleus</td>
<td>Post-splenectomy, hyposplenism (sickle cell disease), neonates, and megaloblastic anemia</td>
</tr>
<tr>
<td>Basophilic Stippling</td>
<td>Deep blue granulations indicating ribosome aggregation</td>
<td>Thalassemia, heavy metal (Pb, Zn, Ag, Hg) poisoning, megaloblastic anemia, MDS, and hereditary (pyrimidine 5’nucleotidase deficiency)</td>
</tr>
<tr>
<td>Sideroblasts</td>
<td>Late erythrocytes in BM with Fe containing granules in the cytoplasm</td>
<td>Hereditary, idiopathic, drugs, EtOH, hypothyroidism (see Sideroblastic Anemia, H16), and myelodysplastic syndrome, toxins (lead)</td>
</tr>
</tbody>
</table>

BM = bone marrow; MF = myelofibrosis; MPN = myeloproliferative neoplasm

Illustrations: Ayalah Hutchins and Merry Shiyu Wang 2012
WHITE BLOOD CELLS

- lymphocytes
  - comprise 30–40% of WBCs; great variation in “normal” lymphocyte morphology
- neutrophils
  - normally, only mature neutrophils (with 3–4 lobed nucleus) and band neutrophils (immediate precursor with horseshoe-shaped nucleus) are found in circulation
  - hypersegmented neutrophil: >5 lobes suggests megaloblastic process (B12 or folate deficiency)
  - left shift (increased granulocyte precursors)
  - seen in leukemoid reactions: acute infections, pregnancy, neonates, hypoxia, shock, and myeloproliferative neoplasms (CML, MF)
- blasts
  - immature, undifferentiated precursors; associated with acute leukemia, MDS, and G-CSF (growth factor that stimulates neutrophil production) use

Table 4. Abnormal White Blood Cells on Film

<table>
<thead>
<tr>
<th>Appearance</th>
<th>Definition</th>
<th>Associated Conditions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Smudge Cell</td>
<td>Lymphocytes damaged during blood film preparation indicating cell fragility</td>
<td>CLL and other lymphoproliferative disorders</td>
</tr>
<tr>
<td>Auer Rod</td>
<td>Cytoplasmic inclusions that form long needles in the cytoplasm of myeloblasts</td>
<td>Pathognomonic for acute myeloid leukemia (AML)</td>
</tr>
<tr>
<td>Atypical Lymphocyte</td>
<td>Pale blue cytoplasm following RBC edges with pink granules</td>
<td>Viruses (particularly EBV) and T-cell large granular lymphocyte leukemia (T-LGL)</td>
</tr>
</tbody>
</table>

EBV = Epstein-Barr virus; CLL = chronic lymphocytic leukemia
Illustrations: Ayahah Hutchins and Merry Shyu Wong 2012 and Danielle Sayeau 2017

PLATELETS

- small, purple, anuclear cell fragments

Bone Marrow Aspiration and Biopsy

- sites: posterior iliac crest/spine, sternum (aspiration only)
- analyses: most often done together
  - aspiration: takes a fluid marrow sample for cellular morphology, flow cytometry, cytogenetics, molecular studies, and microbiology (C&S, acid-fast bacilli, and PCR)
    - note: differential diagnosis for a “dry tap”: MF, hairy cell leukemia, bone marrow infiltration
  - biopsy: takes a sample of intact bone marrow to assess histology (architecture) and immunohistochemistry
  - only aspirates, not biopsies, can be obtained from the sternal site

Indications

- unexplained CBC abnormalities
- diagnosis and evaluation of infiltrating cancers: plasma cell disorders, leukemias, and solid tumours
- diagnosis and staging of lymphoma or solid tumours
- evaluate iron metabolism and stores (gold standard, but rarely done)
- evaluate suspected deposition and storage disease (e.g. amyloidosis, Gaucher’s disease)
- evaluate fever of unknown origin, suspected mycobacterial, fungal, and parasitic infections, or granulomatous disease
- evaluate unexplained splenomegaly
- confirm normal bone marrow in potential allogeneic hematopoietic cell donor

Important Considerations

- consult a hematologist prior to conducting a bone marrow biopsy on a patient with an inherited (e.g. hemophilia, vWF disease) or acquired (e.g. DIC, anticoagulant therapy, coagulopathy of liver disease, and severe thrombocytopenia) bleeding diathesis to determine if pro-hemostatic therapy is indicated pre-procedure
- do not perform a bone marrow biopsy if there is evidence of infection over the targeted skin site
Common Presenting Problems

Anemia

Definition
- a decrease in RBC mass that can be detected by hemoglobin (Hb) concentration, hematocrit (Hct), and RBC count
  - adult males: Hb <130 g/L or Hct <41%
  - adult females: Hb <120 g/L or Hct <36% (changes with pregnancy and trimester)

Clinical Features
- history
  - symptoms of anemia: fatigue, headache, light-headedness, malaise, weakness, decreased exercise tolerance, dyspnea, palpitations, dizziness, tinnitus, and syncope
  - acute vs. chronic, bleeding, systemic illness, diet (Fe, B12 sources), alcohol, and family history
  - menstrual history: menorrhagia, menometrorrhagia
  - rule out pancytopenia (recurrent infection, mucosal bleeding, easy bruising)
- physical signs
  - HEENT: pallor in mucous membranes and conjunctiva at Hb <90 g/L (<9 g/dL), ocular bruits at Hb <55 g/L (<5.5 g/dL), angular cheilitis, jaundice
  - cardiac: tachycardia, orthostatic hypotension, systolic flow murmur, wide pulse pressure, signs of CHF
  - dermatologic: ecchymosis, petechiae, pallor in palm skin creases at Hb <75 g/L, jaundice (if due to hemolysis), nail changes (spooning), and glossitis
  - splenomegaly, lymphadenopathy

Investigations
- rule out dilutional anemia (low Hb due to increased effective circulating volume)
- CBC with differential
- reticulocyte count and blood smear/film
- rule out nutritional deficit, gastrointestinal, and genitourinary disease in iron deficiency anemia
- additional laboratory investigations as indicated (see Microcytic Anemia, H13, Normocytic Anemia, H17, Hemolytic Anemia, H18, and Macrocytic Anemia, H23)
- N.B. may have a mixed picture with multiple concomitant nutritional deficiencies

Erythrocytosis

Definition
- an increase in the number of RBCs: Hb >185 g/L or Hct >52% (males); Hb >165 g/L or Hct >47% (females and African males)

Etiology
- relative/spurious erythrocytosis (decreased plasma volume): diuretics, severe dehydration, burns, and "stress" (Gaisböck’s syndrome)
- absolute erythrocytosis

Hemolysis

- Inherited
  - Hemoglobinopathy (sickle cell disease, thalassemia, unstable Hb)
  - Membrane (spherocytic)
  - Metabolic (HMP shunt, glycolytic pathway)
- Acquired
  - Immune (Combs positive, drug-related, cold agglutinin)
  - Infection (malaria)
  - Microangiopathic hemolytic anemias (DIC, TTP, HELLP)
  - Oxidative/drug-related

Bleeding
- GI
- GU
- Other

Pancytopenia
- Aplastic anemia
- MDS
- Myelofibrosis
- Leukemia
- TB
- Amyloidosis, sarcoidosis
- Drugs (e.g. chemotherapy)
- Bone marrow infiltration
- PNH

Non-pancytopenia
- Anemia of chronic disease
- Renal/liver disease
- Red cell aplasia

Hemolysis

- Inherited
  - Hemoglobinopathy (sickle cell disease, thalassemia, unstable Hb)
  - Membrane (spherocytic)
  - Metabolic (HMP shunt, glycolytic pathway)
- Acquired
  - Immune (Combs positive, drug-related, cold agglutinin)
  - Infection (malaria)
  - Microangiopathic hemolytic anemias (DIC, TTP, HELLP)
  - Oxidative/drug-related

Investigations
- rule out dilutional anemia (low Hb due to increased effective circulating volume)
- CBC with differential
- reticulocyte count and blood smear/film
- rule out nutritional deficit, gastrointestinal, and genitourinary disease in iron deficiency anemia
- additional laboratory investigations as indicated (see Microcytic Anemia, H13, Normocytic Anemia, H17, Hemolytic Anemia, H18, and Macrocytic Anemia, H23)
- N.B. may have a mixed picture with multiple concomitant nutritional deficiencies

<td></td>
<td>Hydronephrosis</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Androgens</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Exogenous erythropoietin</td>
</tr>
</tbody>
</table>

Clinical Features

- secondary to high red cell mass and hyperviscosity
  - headache, dyspnea, dizziness, tinnitus, visual disturbances, hypertensive symptoms, and numbness/tingling
  - symptoms of angina, congestive heart failure, and aquagenic pruritus (only in MPNs)
  - thrombosis (venous or arterial) or bleeding (seen with acquired vWD or acquired platelet dysfunction in MPNs)
  - physical findings
    - splenomegaly ± hepatomegaly, facial plethora/ruddy complexion (70%) and/or palms, gout

Investigations

- serum erythropoietin (EPO): differentiates primary (low/normal) from other etiologies (elevated)
  - search for tumour as source of EPO as indicated (e.g. abdominal U/S, CT head)
  - JAK-2 mutation analysis: positive in >96% of cases of PV
    - only send if low/normal EPO level
  - ferritin (iron deficiency can mask the diagnosis; if iron deficient with reticulocytosis, suggestive of PV)

Treatment

- if primary: see Polycythemia Vera, H42
- if secondary: treat underlying cause
  - O₂ for hypoxemia, CPAP for sleep apnea, surgery for EPO-secreting tumours
  - often cardiologists will be hesitant to treat high Hct in cyanotic patients

Thrombocytopenia

Definition

- platelet count <150 x 10⁹/L

Clinical Features

- history: mucocutaneous bleeding (easy bruising, gingival bleeding), epistaxis, peri-operative bleeding (including dental procedures), heavy menstrual bleeding, and peripartum bleeding
- physical exam: bruising, petechiae, ecchymoses, non-palpable purpura, and wet purpura
- see Disorders of Primary Hemostasis, H27 for complications

Investigations

- CBC and differential
- blood film
  - rule out factitious thrombocytopenia (platelet clumping or platelet satellitism)
  - decreased production: other cell line abnormalities, blasts (suggested myeloid malignancy), hypersegmented PMNs (suggesting megaloblastic anemia), and leukoerythroblastic changes (suggesting BM infiltration or fibrosis)
  - increased destruction: large platelets (often seen in ITP), schistocytes (seen in MAHA/TMA)
  - workup for nutritional deficiencies: B₁₂, RBC folate
  - PT/INR, aPTT, and fibrinogen if DIC suspected
  - LFT
  - abdominal ultrasound to look for splenomegaly

Treatments

- life threatening bleeding: platelet transfusion (repeat CBC 1 h post-transfusion to confirm an appropriate rise in counts)
- if secondary: treat underlying cause
- ITP: see Immune Thrombocytopenic, H27

**Thrombocytosis**

**Definition**
- platelet count >400 x 10⁹/L
- primary thrombocytosis (uncommon): due to myeloproliferative neoplasms (e.g. CML, polycythemia vera, primary myelofibrosis, and essential thrombocytosis; rarely associated with MDS)
- reactive/secondary thrombocytosis (common): acute phase reactant (e.g. surgery, inflammation, infection, trauma, bleeding, iron deficiency, neoplasms, and ischemic injury)

**Clinical Features**
- history: trauma, surgery, splenectomy, infection, inflammation, bleeding, iron deficiency, prior diagnosis of chronic hematologic disorder, and constitutional symptoms (malignancy)
- vasomotor symptoms: headache, visual disturbances, lightheadedness, atypical chest pain, acral dysesthesia, erythromelalgia, livedo reticularis, and aquagenic pruritus
- clotting risk, bleeding risk (rare)
- physical exam: splenomegaly can be seen in myeloproliferative neoplasms (MPNs)

**Investigations**
- CBC, peripheral blood film, serum ferritin concentration
- non-specific markers of infection or inflammation (e.g. CRP, ESR, ferritin)
- if reactive process has been ruled out, bone marrow biopsy may be required to rule out MPN/MDS

**Treatment**
- primary: ASA ± cytotherapeutic agents (e.g. hydroxyurea, anagrelide, interferon-α)
- secondary: treat underlying cause

**Pancytopenia**

**Definition**
- a decrease in all hematopoietic cell lines

**Clinical Features**
- anemia: fatigue (see Anemia, H6)
- leukopenia: recurrent infections (see Neutropenia, H9)
- thrombocytopenia: mucocutaneous bleeding (see Thrombocytopenia, H7)

**Investigations**
- CBC, peripheral blood film, serum ferritin concentration, B12, folate
- non-specific markers of infection or inflammation (e.g. CRP, ESR, ferritin)
- workup as per Figure 4 and presenting symptoms/physical exam
- if reactive process has been ruled out, bone marrow biopsy may be required
Neutrophilia

Definition
- variable definition, but generally an absolute neutrophil count (ANC) >7.7 x 10⁹/L (WHO definition)

Etiology
- primary neutrophilia
  - chronic myeloid leukemia (CML)
  - other myeloproliferative disorders: PV, ET, myelofibrosis
  - hereditary neutrophilia (autosomal dominant)
  - chronic idiopathic neutrophilia in otherwise healthy patients
  - leukocyte adhesion deficiency
- secondary neutrophilia
  - stress/exercise/epinephrine: movement of neutrophils from marginated pool into circulating pool
  - obesity
  - infection: leukocytosis with left shift ± toxic granulation, Döhle bodies (intra-cytoplasmic structures composed of agglutinated ribosomes)
  - inflammation: e.g. rheumatoid arthritis (RA), IBD, chronic hepatitis, MI, PE, and burns
  - malignancy: hematologic (i.e. marrow invasion by tumour) and non-hematologic (especially large cell lung cancer)
  - medications: glucocorticoids, β-agonists, lithium, G-CSF

Clinical Features
- look for signs and symptoms of fever, inflammation, malignancy to determine appropriate further investigations
  - including lymphadenopathy and organomegaly
- examine oral cavity, teeth, peri-rectal area, genitals, and skin for signs of infection

Investigations
- CBC and differential: mature neutrophils or bands >20% of total WBC suggests infection/inflammation
- blood film: Döhle bodies, toxic granulation, and cytoplasmic vacuoles in infection
- may require bone marrow biopsy if MPN suspected

Treatment
- directed at underlying cause

Neutropenia

Definition
- mild: ANC 1.0-1.5 x 10⁹/L
- moderate: ANC 0.5-1.0 x 10⁹/L (risk of infection starts to increase)
- severe: ANC <0.5 x 10⁹/L
- profound: ANC <0.1 x 10⁹/L for >7 d

Absolute Neutrophil Count (ANC) = WBC count x (%PMNs + %bands)
Beware of fever + ANC <0.5 x 10⁹/L = FEBRILE NEUTROPENIA
### Etiology

</tbody>
</table>

### Clinical Features
- fever, chills (only if infection present)
- infection by endogenous bacteria (e.g. S. aureus, Gram negatives from GI and GU tract)
- painful ulceration on skin, anus, mouth, and throat following colonization by opportunistic organisms
- avoid digital rectal exam

### Investigations
- dependent on degree of neutropenia, history, and symptoms
- ranges from observation with frequent CBCs to bone marrow aspiration and biopsy

### Treatment
- regular dental care: chronic gingivitis and recurrent stomatitis are major sources of morbidity
- treatment of febrile neutropenia
- in severe immune-mediated neutropenia, G-CSF may increase neutrophil counts
  - if no response to G-CSF, consider immunosuppression (e.g. steroids, cyclosporine, and methotrexate)

### Lymphocytosis

**Definition**
- absolute lymphocyte count >4.0 x 10⁹/L

**Etiology**
- infection (reactive lymphocytosis)
  - viral infections (majority); particularly mononucleosis
  - TB, pertussis, brucellosis, toxoplasmosis
- smoking
- physiologic response to stress (e.g. trauma, status epilepticus)
- hypersensitivity (e.g. drugs, serum sickness)
- autoimmune (e.g. rheumatoid arthritis)
- neoplasm (e.g. CLL, B cell lymphocytosis of undetermined significance)

**Investigations**
- CBC, peripheral smear assessing lymphocyte morphology

**Treatment**
- treat underlying cause
Lymphopenia

Definition
• absolute lymphocyte count <1.0 x 10⁹/L

Etiology
• older age
• idiopathic CD4+ lymphocytopenia
• radiation
• HIV/AIDS, hepatitis B, hepatitis C
• malignancy/chemotherapeutic agents
• malnutrition, alcoholism
• autoimmune disease (e.g. SLE)

Clinical Features
• opportunistic infections (see Infectious Diseases, ID32)

Treatment
• treat underlying cause
• treat opportunistic infections aggressively and consider antimicrobial prophylaxis (see Infectious Diseases, ID28)

Eosinophilia

Definition
• absolute eosinophil count >0.5 x 10⁹/L

Etiology
• primary: due to clonal bone marrow disorder
  - if no primary etiology identified, classified as hypereosinophilic syndrome
  - 6 mo of eosinophilia (count >1.5 x 10⁹/L) with no other detectable causes and end organ damage
  - can involve heart, bone marrow, and CNS
• secondary
  - most common causes are parasitic (usually helminth) infections and allergic reactions
  - less common causes
    - collagen vascular diseases (e.g. RA, polyarteritis nodosa, see Rheumatology, RH20)
    - respiratory causes (asthma, eosinophilic pneumonia, and Churg-Strauss)
    - cholesterol emboli
    - hematologic malignancy: see Chronic Myeloid Leukemia, H40 and Hodgkin Lymphoma, H45
    - adrenal insufficiency: see Endocrinology, E36
    - medications (penicillins)
    - atopic dermatitis

Treatment
• treat underlying cause
• ensure strongyloides serology is collected to rule out infection before initiating steroids for patients at risk

Agranulocytosis

Definition
• absolute neutrophil count is <100/µL per microlitre

Etiology
• associated with medications in 70% of cases: e.g. chemotherapy, clozapine, thionamides (antithyroid drugs), sulfasalazine, and ticlopidine
  - immune-mediated destruction of circulating granulocytes by drug-induced antibodies or direct toxic effects upon marrow granulocytic precursors

Clinical Features
• abrupt onset of fever, chills, weakness, and oropharyngeal ulcers

Prognosis
• high fatality without vigorous treatment

Investigations/Treatment
• discontinue offending drug
• pan-culture and screen for infection if patient is febrile (blood cultures x2, urine culture, and chest x-ray as minimum, initiate broad-spectrum antibiotics)
• consider bone marrow aspirate and biopsy if cause unclear
• consider G-CSF
Leukemoid Reaction

- blood findings resembling those seen in certain types of leukemia which reflect the response of healthy BM to cytokines released due to infection or trauma
- leukocytosis >50 x 10⁹/L, marked left shift (myelocytes, metamyelocytes, and bands in peripheral blood smear)

Approach to Lymphadenopathy

History
- constitutional/B-symptoms: seen in TB, lymphoma, other malignancies
- growth pattern: acute vs. chronic
- exposures: cats (cat scratch – *Bartonella henselae*), ticks (Lyme disease – *Borrelia burgdorferi*), and high risk behaviours (HIV)
- joint pain/swelling, rashes (connective tissue disorder)
- pruritus (seen in Hodgkin lymphoma)
- medications (can cause serum sickness → lymphadenopathy)

Clinical Features
- determine if lymphadenopathy is localized or generalized
- localized: typically reactive or neoplastic
  - cervical (bacterial/mycobacterial infections, ENT malignancies, and metastatic cancer)
  - supravacular
    - right (mediastinal, bronchogenic, esophageal cancer)
    - left (gastric, gall bladder, pancreas, renal, and testicular/ovarian cancer)
  - axillary (cat scratch fever, breast cancer, and metastatic cancer)
  - epitrochlear (infections, sarcoidosis, and lymphoma)
  - check for splenomegaly, constitutional symptoms

Investigations
- CBC and differential, blood film
- if generalized, consider tuberculin test, HIV RNA, VDRL, Monospot*/EBV serology, ANA, and imaging
- if localized and no symptoms suggestive of malignancy, can observe 3–4 wk (if no resolution → biopsy)
- excisional biopsy is preferred as it preserves node architecture (essential for diagnosing lymphoma)
- in areas difficult to access (retroperitoneal, mediastinal/hilar) multiple core biopsies may be more practical/feasible
- FNA should NOT be used for diagnostic purposes in lymphoproliferative disease (excisional biopsy is the gold standard)
  - FNA is helpful for recurrence of solid tumour malignancy
  - imaging such as U/S or CT can provide more info, but generally adds little to diagnosis

Table 7. Inflammatory vs. Neoplastic Lymph Nodes

<table>
<thead>

The **underlined** conditions cause massive splenomegaly (spleen crosses midline or reaches pelvis)

**History**
- constitutional symptoms, feeling of fullness in LUQ, and early satiety
- signs or symptoms of infection (e.g. mononucleosis) or malignancy
- history of liver disease, hemolytic anemia, or high-risk exposures

**Clinical Features**
- jaundice, petechiae
- signs of chronic liver disease
- percussion (Castell's sign, Traube's space, and Nixon's method) and palpation
- associated lymphadenopathy or hepatomegaly
- signs of CHF

**Investigations**
- CBC and differential, blood film
- as indicated: liver enzymes (AST, ALT, ALP, and GGT) and/or LFTs (platelet, INR, albumin, and bilirubin), reticulocyte count, Monospot/EBV, haptoglobin, LDH, infectious, and autoimmune workup
- imaging
  - ultrasound of abdomen/liver to assess for cirrhosis and portal vein thrombosis (if positive, refer to hepatology)
  - echo for cardiac function
  - CT to rule out lymphoma and assess splenic lesions

**Microcytic Anemia**

- MCV <80 fL
- see Figure 2, Approach to Anemia, H6

**Iron Metabolism**

**Iron Intake (Dietary)**
- average North American adult diet = 10-20 mg iron (Fe) daily
- steady state absorption is 5-10% (0.5-2 mg/d); enhanced by citric acid, ascorbic acid (vitamin C) and reduced by polyphenols (e.g. in tea), phytate (e.g. in bran), dietary calcium, and soy protein
- males more likely to have positive Fe balance; up to 20% of menstruating females have negative Fe balance
Iron Absorption and Transport
- dietary iron is absorbed in the duodenum (e.g. absorption impaired in IBD and Celiac disease)
- in circulation the majority of non-heme iron is bound to transferrin which transfers iron from enterocytes and storage pool sites (macrophages of the reticuloendothelial system and hepatocytes) to RBC precursors in the bone marrow

Iron Levels
- hepcidin is a hormone produced by hepatocytes that regulates systemic iron levels
  - binds to iron exporter ferroportin (on duodenal enterocytes and reticuloendothelial cells) and induces its degradation, thereby inhibiting iron export into circulation (diminished absorption of iron and iron trapping in reticuloendothelial system cells)
  - hepcidin production is:
    - increased in states of iron overload (inhibiting additional iron absorption) and inflammation (mediating anemia of chronic inflammation through iron trapping)
    - decreased in states where erythropoiesis is increased (e.g. hemolysis) or oxygen tension is low

Iron Storage
- ferritin
  - ferric iron (Fe³⁺) complexed to a protein called apoferritin (liver, spleen, and bone marrow are main ferritin storage sites)
  - small quantities are present in plasma in equilibrium with intracellular ferritin
  - also an acute phase reactant – can be spuriously elevated despite low Fe stores in response to a stressor
- hemosiderin
  - aggregates or crystals of ferritin with the apoferritin partially removed
  - macrophage-monocyte system is main source of hemosiderin storage

**Figure 5. Iron metabolism**

Iron Indices
- bone marrow aspirate: gold standard test for assessment of iron stores (rarely done)
- serum ferritin: most important blood test for iron stores
  - decreased in iron deficiency anemia
  - elevated in infection, inflammation, malignancy, liver disease, hyperthyroidism, and iron overload
- serum iron: measure of all non-heme iron present in blood
  - varies significantly daily
- total iron binding capacity (TIBC): indirect measure of total amount of transferrin present in blood
  - normally, one third of TIBC is saturated with iron
  - increased TIBC has high specificity for decreased iron, low sensitivity
- saturation
  - serum Fe divided by TIBC, expressed as a proportion or a percentage
- soluble transferrin receptor (sTfR)
  - reflects the availability of iron at the tissue level
  - the transferrin receptor is expressed on the surface of erythroblasts and is responsible for iron uptake – some are cleaved off and are present in circulation as sTfR
  - in iron deficient states more transferrin receptors are expressed on erythroblasts leading to an increase in sTfR
  - low in reduced erythropoiesis and iron overload
- useful in determining iron deficiency in the setting of chronic inflammatory disorders (see Iron Deficiency Anemia, H15)
Iron Deficiency Anemia

- see Pediatrics, P43
- most common cause of anemia in North America

Etiology
- increased demand
  - increased physiological need for iron in the body (e.g., pregnancy)
- decreased supply: dietary deficiencies (rarely the only etiology in the developed world)
  - cow’s milk (infant diet), “tea and toast” diet (elderly), absorption imbalances, post-gastrectomy, malabsorption (IBD of duodenum, celiac disease, autoimmune atrophic gastritis, and H.pylori infection)
- increased losses
  - hemorrhage
    - obvious causes: menorrhagia, abnormal uterine bleeding, and frank GI bleed
    - occult: peptic ulcer disease, GI cancer
  - hemolysis
    - chronic intravascular hemolysis (e.g., PNH, cardiac valve RBC fragmentation)

Clinical Features
- iron deficiency may cause fatigue before clinical anemia develops
- signs/symptoms of anemia: see Anemia, H6
- brittle hair, nail changes (brittle, koilonychia)
- pica (appetite for non-food substances e.g., ice, paint, and dirt)
- restless leg syndrome

Investigations
- iron indices, including soluble transferrin receptor
  - low ferritin (<18 µg/L) is diagnostic of iron deficiency
  - ferritin is an acute phase reactant and is elevated in the setting of inflammatory conditions and liver disease; serum ferritin <100 µg/L in these settings is suggestive of iron deficiency, necessitating further workup
- peripheral blood film
  - hypochromic microcytosis: RBCs have low Hb levels due to lack of iron
  - pencil forms, anisocytosis
  - target cells
- bone marrow (gold standard but rarely done)
  - iron stain (Prussian blue) shows decreased iron in macrophages and in erythroid precursors (sideroblasts)
  - intermediate and late erythroblasts show micronormoblastic maturation

**Figure 6. Approach to interpreting iron indices**
Adapted from: Am Fam Physician 2007;75:671-678

Treatment
- treat underlying cause
- supplementation
  - oral (capsules, syrup)
    - ferrous sulphate 325 mg OD (65 mg elemental iron), ferrous gluconate 300 mg OD (35 mg elemental iron), or ferrous fumarate 300 mg OD (100 mg elemental iron), polysaccharide iron complex (150 mg elemental iron), heme iron polypeptide (11 mg elemental iron)
    - supplement until anemia corrects, then continue for 3+ mo until serum ferritin returns to normal
    - recent studies demonstrate alternate day dosing may be superior to daily or more frequent dosing, due to improved absorption, though this is still an area of investigation
    - oral iron should be taken with citrus juice (vitamin C) to enhance absorption
  - IV (iron sucrose or dextran) can be considered if patient cannot tolerate or absorb oral iron
- monitoring response
  - reticulocyte count will begin to increase after one wk
  - Hb normalizes by 10 g/L per wk (if no blood loss)
Anemia of Chronic Inflammation

Etiology
- infection, malignancy, inflammatory, and rheumatologic disease
- chronic renal and liver disease
- endocrine disorders (e.g. DM, hypothyroidism, hypogonadism, and hypopituitarism)

Pathophysiology
- an anemia of underproduction due to impaired iron utilization (hepcidin is a key regulatory peptide)
  - hepatic hepcidin production is increased in inflammatory processes, trapping iron in enterocytes and macrophages (via ferroportin inhibition), see Figure 5
  - reduced plasma iron levels make iron relatively unavailable for new hemoglobin synthesis
  - marrow unresponsive to normal or slightly elevated EPO
- mild hemolytic component is often present i.e. RBC survival is modestly decreased

Investigations
- diagnosis of exclusion
- associated with elevation in acute phase reactants (ESR, CRP, fibrinogen, and platelets)
- peripheral blood
  - mild: usually normocytic and normochromic
  - moderate: may be microcytic and normochromic
  - severe: may be microcytic and hypochromic
  - absolute reticulocyte count is frequently low, reflecting overall decrease in RBC production
- “classic” serum iron indices
  - serum iron and TIBC low or normal, % saturation low
  - serum ferritin is normal or increased
- bone marrow
  - normal or increased iron stores
  - decreased or absent staining for iron in erythroid precursors

Treatment
- treat underlying disease; only treat in patients who would benefit from a higher hemoglobin
- IV iron if no benefit from PO iron (overcomes sequestration in enterocytes)
- erythropoietin indicated in chronic renal failure; not to be used if patient has concomitant curative solid tumour malignancy; ensure Hb target <110 g/L

Sideroblastic Anemia

- uncommon compared to iron deficiency anemia or anemia of chronic disease

Sideroblasts
- erythrocytes with iron-containing (basophilic) granules in the cytoplasm
- “normal”: granules are small and randomly spread in the cytoplasm
- “ring”: iron deposits in mitochondria, forming large, abnormal granules that surround the nucleus
- the hallmark of sideroblastic anemia

Etiology
- due to defects in heme biosynthesis in erythroid precursors
- hereditary (rare); X-linked; median survival 10 yr
- idiopathic (acquired)
  - refractory anemia with ringed sideroblasts: a subtype of MDS (see Myelodysplastic Syndromes, H39)
    - may be a preleukemic phenomenon (1-2% transform to AML)
  - reversible
    - drugs (isoniazid, chloramphenicol), alcohol, lead, copper deficiency, zinc toxicity, and hypothyroidism

Clinical Features
- anemia symptoms (see Anemia, H6)
- hepatosplenomegaly, evidence of iron overload

Investigations
- serum iron indices
  - increased serum Fe**, normal TIBC, increased ferritin, increased sTfR
- blood film/bone marrow biopsy
  - ringed sideroblasts (diagnostic hallmark)
  - RBCs are hypochromic; can be micro-, normo-, or macrocytic
  - anisocytosis, poikilocytosis, basophilic stippling

Treatment
- depends on etiology
  - X-linked: high dose pyridoxine (vitamin B6) in some cases
  - acquired: EPO and G-CSF
  - reversible: remove precipitating cause
  - supportive transfusions for severe anemia
**Lead Poisoning**

**Definition/Etiology**
- blood lead levels greater than 80 µg/dL, possible symptomatology at 50 µg/dL
- identify source: consider occupational history, exposures history, and utensil history

**Clinical Features**
- abdominal pain, constipation, irritability, and difficulty concentrating

**Treatment**
- chelation therapy: dimercaprol and EDTA are first line agents

---

**Normocytic Anemia**

- MCV 80-100 fL
- see Figure 2, *Approach to Anemia, H6*

**Aplastic Anemia**

**Definition**
- destruction of hematopoietic cells of the bone marrow leading to pancytopenia and hypocellular bone marrow

**Etiology**

**Table 11. Etiology of Aplastic Anemia**

<table>
<thead>
<tr>

</tbody>
</table>

**Clinical Features**
- can present acutely or insidiously
- symptoms of anemia (see *Anemia, H6*), thrombocytopenia (see *Thrombocytopenia, H7*), and/or infection
- ± splenomegaly and lymphadenopathy (depending on the cause)

**Investigations**
- exclude other causes of pancytopenia (see *Figure 4*), including PNH (50% of AA patients have PNH+ stem cell clones)
- CBC
  - anemia, neutropenia or thrombocytopenia (any combination) ± pancytopenia
  - decreased reticulocytes (<1% of the total RBC count)
- blood film
  - decreased number of normal RBCs
- bone marrow
  - aplasia or hypoplasia of marrow cells with fat replacement
  - decreased cellularity

**Treatment**
- remove offending agents
- supportive care (red cell and platelet transfusions, antibiotics)
  - judicious use so as to not increase the risk of immune sensitization to blood products
  - iron chelation therapy for iron overload (build up of iron after multiple >20 units of blood transfusion)
- immunosuppressive therapy (for idiopathic aplastic anemia)
  - horse or rabbit anti-thymocyte globulin: 40-50% of patients respond
  - + cyclosporine (for improved response and survival)
- allogeneic bone marrow transplant
- growth factors: e.g. Eltrombopag (TPO receptor agonist), G-CSF, and EPO not effective
Hemolytic Anemia

Definition
- anemia due to a shortened survival of circulating RBCs, usually defined as <100 d
- uncommon cause for anemia (<5% of cases) with many etiologies (>200)

Classification
- hereditary
  - abnormal membrane (spherocytosis, elliptocytosis)
  - abnormal enzymes (pyruvate kinase deficiency, G6PD deficiency)
  - abnormal hemoglobin synthesis (thalassemias, hemoglobinopathies)
- acquired
  - immune
    - autoimmune: warm vs. cold autoimmune hemolytic anemias (AIHA), see Table 14 Classification of AIHA, H22
  - alloimmune: hemolytic disease of the fetus/newborn and post-transfusion
- non-immune
  - MAHA/TMA, now known as TMA: thrombus in blood vessel causes RBCs to be sheared – associated with DIC, HUS, aHUS, TTP, preeclampsia/HELLP, vasculitides, and malignant hypertension
  - other causes: PNH, hypersplenism, march hemoglobinuria (exertional hemolysis), infection (e.g. malaria), snake venoms, and mechanical heart valves
- also classified as intravascular or extravascular
  - intravascular: MAHA/TMA (e.g. TTP, DIC), infections (malaria, Clostridium), and PNH
  - extravascular: RBCs are coated with antibodies (AIHA) or have an abnormal membrane structure/shape or inclusions

Clinical Features Specific to HA
- jaundice
- dark urine (hemoglobinuria, bilirubin)
- cholelithiasis (pigment stones)
- potential for an aplastic crisis (i.e. BM suppression in overwhelming infection)
- iron overload with extravascular hemolysis
- iron deficiency with intravascular hemolysis

Investigations

</tbody>
</table>

Tests Specific for Extravascular Hemolysis

Direct Antiglobulin Test (DAT) (direct Coombs)
- Detects IgG or complement on the surface of RBC
- Add anti-IgG or anti-complement Ab to patient's RBCs; positive if agglutination
- Indications: hemolytic disease of newborn, AIHA, hemolytic transfusion reaction

Indirect Antiglobulin Test (indirect Coombs)
- Detects antibodies in serum that can recognize antigens on RBCs
- Mix patient's serum + donor RBCs + Coombs serum (anti-human Ig Ab); positive if agglutination
- Indications: cross-matching donor RBCs, atypical blood group, blood group Ab in pregnant women, AIHA
Hemolytic Anemia

**Thalassemia**

**Definition**
- defects in production of the α or β chains of hemoglobin
  - resulting imbalance in globin chains leads to ineffective erythropoiesis and hemolysis in the spleen or BM
  - clinical manifestations and treatment depend on specific gene and number of alleles affected
- common features
  - increasing severity with increasing number of alleles involved
  - hypochromic microcytic anemia
  - basophilic stippling, abnormally shaped RBCs on blood film

**Pathophysiology**
- defect may be in any of the Hb genes
  - normally 4α genes in total; 2 on each copy of chromosome 16
  - normally 2β genes in total; 1 on each copy of chromosome 11
  - fetal hemoglobin, HbF (α2γ2), switches to adult forms HbA (α2β2) and HbA2 (α2δ2) at 3-6 mo of life
  - HbA constitutes 97% of adult hemoglobin
  - HbA2 constitutes 3% of adult hemoglobin

**β-Thalassemia Minor (Thalassemia Trait)**

**Definition**
- defect in single allele of β gene (heterozygous for one normal β globin allele and one β globin thalassemic allele)
- common in people of Mediterranean and Asian descent

**Clinical Features**
- usually asymptomatic; a palpable spleen is very rare

**Investigations**
- Hb (100-140 g/L), MCV (<70 fL), Fe (normal), RBC count (normal)
- peripheral blood film – microcytosis basophilic stippling
- Hb electrophoresis
  - specific: HbA2 increased to 3.5-5% (normal 1.5-3.5%)
  - non-specific: 50% have slight increase in HbF

**Treatment**
- no treatment required
- genetic counselling for patient and family

**β-Thalassemia Major**

**Definition**
- defect in both alleles of β gene (homozygous, autosomal recessive)

**Pathophysiology**
- ineffective chain synthesis leading to ineffective erythropoiesis, hemolysis of RBCs, and increase in HbF

**Clinical Features**
- initial presentation at age 6-12 mo when HbA (α2/β2) normally replaces HbF (α2/γ2)
  - severe anemia, jaundice
  - iron overload due to compensatory gastrointestinal iron uptake progressing to hemochromatosis
  - secondary to repeated transfusions and ineffective erythropoiesis
  - leads to iron-induced organ damage
  - stunted growth and development (hypogonadal dwarf)
  - gross hepatosplenomegaly (due to extramedullary hematopoiesis)
  - radiologic changes (due to expanded marrow cavity) and extramedullary hematopoietic masses (erythroid tissue tumours)
    - skull x-ray has “hair-on-end” appearance
    - pathologic fractures common
  - evidence of increased Hb catabolism (e.g. pigmented gallstones)
  - death can result from:
    - untreated anemia (should transfuse)
    - infection (should identify and treat early)
    - iron overload (common): late complication from repeated transfusions and ineffective erythropoiesis

**Investigations**
- severe microcytic anemia (Hb <60 g/L)
- peripheral blood film: teardrop, target, hypochromatic, microcytic
- Hb electrophoresis
  - HbA: 0-10% (normal >95%)
  - HbA2 >2.5%
  - HbF: 90-100%

**Hemochromatosis Clinical Features**
- Arthralgia
- Bronze skin
- Cardiomyopathy, cirrhosis of liver
- Diabetes (pancreatic damage)
- Hypogonadism (anterior pituitary damage)
**Hematology**

**Hemolytic Anemia**

**Treatment**
- Lifelong regular transfusions to suppress endogenous erythropoiesis
- Iron chelation (e.g., deferoxamine, deferasirox, and deferiprone) to prevent iron overload in organs and the formation of free radicals (which promote tissue damage and fibrosis)
- Folic acid supplementation if not transfused
- Allogeneic bone marrow transplantation (potentially curative) or cord blood transplant
- Splenectomy (now performed less frequently)

**β-Thalassemia Intermedia**

**Definition**
- Clinical diagnosis in patients whose clinical manifestations are too mild to be classified as thalassemia major, but too severe to be classified as thalassemia minor

**Clinical Features**
- Wide variety of clinical phenotypes
- In most cases of thalassemia intermedia, both β-globin genes affected
- Three main mechanisms account for the milder phenotype compared to thalassemia major: (1) subnormal (vs. absent) β-chain synthesis, (2) increased number of γ chains, (3) coinheritance of α thalassemia (in some cases)
- Complications more commonly seen in thalassemia intermedia than thalassemia major include extramedullary hematopoiesis, leg ulcers, gallstones, thrombosis, pulmonary hypertension, and growth retardation

**Treatment**
- Most patients only require periodic transfusions, although regular transfusions may eventually be necessary in adulthood (third to fourth decade of life)
- Folic acid supplementation if not transfused
- Due to ineffective erythropoiesis leading to downregulation of hepcidin, iron chelation therapy is required since iron overload develops even without frequent transfusion

**α-Thalassemia**

**Definition**
- Defect(s) in α genes
- Similar geographic distribution as β-thalassemia, but higher frequency among Asians and Africans

**Clinical Features**
- 1 defective α gene (aa/a-): Clinically silent; normal Hb, normal MCV
- 2 defective α genes (cis: aa/- or trans: a/-a): Decreased MCV, normal Hb
  - N.B. cis 2-gene deletion more common in Asia vs. trans 2-gene deletion more common in Africa – this leads to increased risk of fetal hydrops in offspring of Asian patients vs. African patients
- 3 defective α genes (a/-/-): HbH (β4) disease; presents in adults, decreased MCV, decreased Hb, and splenomegaly
- 4 defective α genes (a/-/-/-): Hb Bart's (γ4) disease (hydrops fetalis); usually incompatible with life

**Investigations**
- Peripheral blood film – Screen for HbH inclusion bodies with supravital stain
- Electrophoresis can be used to identify HbH disease, but may miss 1- or 2-gene deletions; definitive diagnosis with DNA genotyping

**Treatment**
- Depends on degree of anemia, referral for genetic/prenatal counselling
  - 1 or 2 defective α genes: No treatment required
  - HbH disease: similar to β-thalassemia intermedia
  - Hb Bart's: No definitive treatment, majority of pregnancies terminated (fetal/maternal mortality risk), and intrauterine transfusion, stem cell transplants

**Sickle Cell Disease**

**Definition**
- Autosomal recessive sickling disorders arise due to a mutant β-globin chain, most commonly caused by a Glu → Val substitution at position 6 (chromosome 11) resulting in HbS variant, rather than HbA (normal adult Hb)
  - Increased incidence of HbS allele with Sub-Saharan African, Indian, Middle Eastern or Mediterranean heritage (thought to be protective against malaria)
  - Sickle cell disease occurs when an individual has two HbS genes (homozygous, HbSS) or one HbS gene + another mutant β-globin gene (compound heterozygote) – Most commonly HbS-β-thal and HbSC disease

**Pathophysiology**
- At low PO2, deoxy HbS polymerizes leading to rigid crystal-like rods that distort membranes → ‘sickles’
- The PO2 level at which sickling occurs is related to the percentage of HbS present
- Sickle cell-aggravated by acidemia, increased CO2, increased 2,3-DPG, fever, and osmolality

---

**Figure 8. Pathophysiology of sickling**

**Functional asplenism:** increased susceptibility to infection by encapsulated organisms
- S. pneumoniae
- N. meningitidis
- H. influenzae
- Salmonella (osteomyelitis)
- fragile sickle cells then cause injury in two main ways
  1. fragile sickle cells hemolyze (nitric oxide depletion)
  2. occlusion of small vessels (hypoxia, ischemia-reperfusion injury)

**Clinical Features**
- \text{HbAS} (sickle cell trait): patient will be asymptomatic except during extreme hypoxia or infection
  - increased risk of renal medullary carcinoma
- \text{SCD-SS} (HbSS)
  - chronic hemolytic anemia
  - jaundice in the first year of life
  - retarded growth and development ± skeletal changes
  - splenomegaly in childhood; splenic atrophy in adulthood
- \text{SCD-SS} often presents with acute pain episode
  1. aplastic crises
     - toxins and infections (especially parvovirus B19) transiently suppress bone marrow
  2. splenic sequestration crises
     - usually in children; significant pooling of blood in spleen resulting in acute Hb drop and shock
     - uncommon in adults due to asplenia from repeated infarction
  3. vaso-occlusive crises (infarction)
     - may affect various organs causing ischemia-reperfusion injury (especially in back, chest, abdomen, and extremities), fever, and leukocytosis
     - can cause a stroke or a silent myocardial infarction
     - precipitated by infections, dehydration, rapid change in temperature, pregnancy, menses, and alcohol
  4. acute chest syndrome
- \text{SCD-SC} (most common compound heterozygote)
  - 1:833 live births in African-Americans, common in West Africa
  - milder anemia than HbSS
  - similar complications as HbSS, although typically milder and less frequent (exception is proliferative sickle retinopathy, glomerulonephritis, and avascular necrosis)
  - spleen not always atrophic in adults

**Investigations**
- sickle cell prep (detects sickling of RBCs under the microscope in response to O2 lowering agent): determines the presence of a HbS allele, but does not distinguish HbAS from HbSS
- \text{Hb electrophoresis} distinguishes HbAS, HbSS, HbSC, and other variants
- all newborns in developed countries typically screened for SCD

<td>No HbA, only HbS and HbF (proportions change with age); normal amount of HbA2</td>
</tr>
</tbody>
</table>

**Treatment**
- genetic counselling
- \text{HbAS}: no treatment required
- \text{HbSS}: treatment as per HbSS, but is dictated by symptom severity
- \text{HbSS}:
  1. folic acid to prevent folate deficiency
  2. hydroxyurea to enhance production of HbF
     - mechanism of action: stops repression of Hb-γ chains and/or initiates differentiation of stem cells in which this gene is active
     - presence of HbF in the SS cells decreases polymerization and precipitation of HbS
     - N.B. hydroxyurea is cytotoxic and may cause bone marrow suppression
  3. treatment of vaso-occlusive crisis
     - supportive care: oxygen, hydration (reduces viscosity), correct acidosis, analgesics/opiates
     - indication for exchange transfusion: Hb <50-60 g/L, SCD complications (acute chest syndrome, aplastic crisis, hepatic or splenic sequestration, stroke), prevention of complications, pre-operative
     - less routinely: antimicrobials for suspected infection
  4. prevention of crises
     - establish diagnosis
     - avoid conditions that promote sickling (hypoxia, acidosis, dehydration, fever)
     - vaccination in childhood (pneumococcus, meningococcus, H. influenzae b)
     - prophylactic penicillin (age 3 mo-5 yr)
     - good hygiene, nutrition, and social support

**NIH Consensus Development Conference Statement: Hydroxyurea Treatment for Sickle Cell Disease**

*Ann Intern Med 2008;148:932-938*

**Efficacy:** Strong evidence for adolescents and adults and there is emerging data supporting its use in children. In the single RCT, the Hb level was higher in hydroxyurea recipients than placebo recipients after 2 yr (difference, 6 g/L), as was HbF (absolute difference, 3.2%). The median number of painful crises was 44% lower than in the placebo arm. The 12 observational studies that enrolled adults reported a relative increase in HbF of 4-20% and a relative reduction in crisis rates by 68-84%. Hospital admissions declined by 18-32%.

**Effectiveness:** Data is limited. It seems to be highly effective but is currently underutilized.

**Short-Term Harms (within 6 mo):** Dose-related leukopenia, thrombocytopenia, anemia, and decreased reticulocyte count. Others include decreased sperm production and dry skin.

**Long-Term Harms:** Birth defects in offspring of people receiving the drug, growth delays in children receiving the drug, and cancer in both children and adults who receive the drug.
5. screen for complications
- regular blood work (CBC, reticulocytes, iron indices, BUN, LFTs, and creatinine)
- urinalysis annually (proteinuria and glomerulopathy)
- transcranial doppler annually until 16 yr old (stroke prevention)
- retinal examinations annually from 8 yr old (screen for retinopathy)
- echocardiography once in late childhood/early adulthood (screen for pulmonary hypertension)

### Microangiopathic Hemolytic Anemia

#### Thrombotic Microangiopathy

**Definition**
- hemolytic anemia due to intravascular fragmentation of RBCs

**Etiology**
- see Thrombotic Thrombocytopenic Purpura and Hemolytic Uremic Syndrome, H30
- see Disseminated Intravascular Coagulation, H32
- eclampsia, HELLP syndrome, AFLP
- malignant hypertension
- vasculitis
- malfunctioning heart valves
- metastatic carcinoma
- drugs (calcineurin inhibitors, quinine, simvastatin)
- infections (severe CMV or meningococcus)
- catastrophic antiphospholipid antibody syndrome

**Investigations**
- blood film: evidence of hemolysis, schistocytes
- hemolytic workup (CBC, reticulocyte count, LDH, haptoglobin, indirect bilirubin)
- Coombs’s test negative
- urine: hemosiderinuria, hemoglobinuria

### Hereditary Spherocytosis

- most common type of hereditary hemolytic anemia
- abnormality in RBC membrane proteins (e.g. spectrin)
  - spleen makes defective RBCs more spherocytic (and more fragile) by membrane removal; also acts as site of RBC destruction
  - autosomal dominant with variable penetrance

**Investigations**
- blood film (shows spherocytes), osmotic fragility (increased), molecular analysis for spectrin gene

**Treatment**
- in severe cases, splenectomy and vaccination against pneumococcus, meningococcus, and H. influenza type b (avoid in early childhood)
**Hereditary Elliptocytosis**

**Definition/Etiology**
- abnormality in spectrin interaction with other membrane proteins
- autosomal dominant
- 25-75% elliptocytes
- hemolysis is usually mild

**Treatment**
- immunizations; splenectomy for severe hemolysis

---

**Glucose-6-Phosphate Dehydrogenase Deficiency**

**Definition**
- deficiency in glucose-6-phosphate dehydrogenase (G6PD), corresponding to a lack of reduced glutathione (GSH) and leading to RBC sensitivity due to oxidative stress

**Pathophysiology**
- X-linked recessive, prevalent in individuals of African, Asian, and Mediterranean descent

**Clinical Features**
- frequently presents as episodic hemolysis precipitated by:
  - oxidative stress
  - drugs (e.g. sulfonamide, antimalarials, nitrofurantoin)
  - infection
  - food (fava beans)
- in neonates: can present as prolonged, pathologic neonatal jaundice

**Investigations**
- neonatal screening
- G6PD assay (may not be useful if result is normal)
- blood film
  - Heinz bodies (granules in RBCs due to oxidized Hb); passage through spleen results in the generation of bite cells
  - may have features of intravascular hemolysis (e.g. RBC fragments)

**Treatment**
- folic acid
- stop offending drugs and avoid triggers
- transfusion in severe cases

---

**Macrocytic Anemia**

- MCV >100 fl
- see Figure 2, Approach to Anemia, H6

**Table 15. Comparison Between Megaloblastic and Non-Megaloblastic Macrocytic Anemia**

<table>
<thead>
<tr>

<tr>
<td><strong>Pathophysiology</strong></td>
<td>Failure of DNA synthesis resulting in asynchronous maturation of RBC nucleus and cytoplasm</td>
<td>Reflects membrane abnormality with abnormal cholesterol metabolism</td>
</tr>
</tbody>
</table>

---

**Causes of Macrocytic Anemia**
- A: Alcoholism (liver disease)
- B: B12 deficiency
- C: Compensatory reticulocytosis
- D: Drugs (cytotoxic, AZT) / Dysplasia
- E: Endocrine (hypothyroidism)
- F: Folate deficiency / Fetus (pregnancy)

**Characteristics of Megaloblastic Macrocytic Anemia**
- Pancytopenia
- Hypersegmented neutrophils
- Megaloblastic bone marrow
Vitamin B₁₂ Deficiency

- B₁₂ (cobalamin)
- binds to intrinsic factor (IF) secreted by gastric parietal cells
- absorbed in terminal ileum
- total body stores sufficient for 3-4 yr

Etiology

### Table 16. Etiology of Vitamin B₁₂ Deficiency

<table>
<thead>
<tr>

</tr>
<tr>
<td>Malnutrition</td>
<td></td>
<td>Neomycin, biguanides, PPI, N₆.anesthesia, metformin</td>
<td></td>
</tr>
</tbody>
</table>

Pathophysiology of Pernicious Anemia

- auto-antibodies produced against gastric parietal cells leading to achlorhydria and lack of intrinsic factor secretion
- intrinsic factor is required to stabilize B₁₂ as it passes through the bowel
- decreased intrinsic factor leads to decreased ileal absorption of B₁₂
- may be associated with other autoimmune disorders (polyglandular endocrine insufficiency)
- most common in Northern European Caucasians, usually >30 yr old (median age of 60 yr old)

Clinical Features

- neurological (severity of anemia and neurological sequelae depends on deficiency)
  - peripheral neuropathy (variable reversibility)
  - usually symmetrical, affecting lower limbs more than upper limbs
  - cord (irreversible damage)
  - subacute combined degeneration
    - posterior columns: decreased vibration sense, proprioception, 2-point discrimination, and paresthesia
    - pyramidal tracts: spastic weakness, ataxia
  - cerebral (common, reversible with B₁₂ therapy)
    - confusion, delirium, and dementia
  - cranial nerves (rare)
    - optic atrophy

Investigations

- CBC, reticulocyte count
  - anemia often severe ± neutropenia ± thrombocytopenia
  - MCV >110 fL
  - low reticulocyte count relative to the degree of anemia (<2%)
- serum B₁₂ and RBC folate
  - caution: low serum B₁₂ leads to low RBC folate because of failure of folate polyglutamate synthesis in the absence of B₁₂
  - alternatively, can measure elevated urine metabolites (methylmalonate, homocysteine)
- blood film
  - oval macrocytes, hypersegmented neutrophils
- bone marrow
  - hypercellularity
  - nuclear-cytoplasmic asynchrony in RBC precursors (less mature nuclei than expected from the development of the cytoplasm)
- bilirubin and LDH
  - elevated unconjugated bilirubin and LDH due to breakdown of cells in BM
- Schilling test (radiolabeled B₁₂ test, rarely done) to distinguish pernicious anemia from other causes
  - anti-intrinsic factor antibody, anti-parietal cell antibody

Treatment

- vitamin B₁₂: 1000 µg IM or 1000-1200 µg PO if intestinal absorption intact, route and duration depends on cause
- less frequent, higher doses may be as effective (e.g. 1000 µg IM q3mo)
- watch for hypokalemia and rebound thrombocytosis when treating severe megaloblastic anemia

Oral Vitamin B₁₂ vs. Intramuscular Vitamin B₁₂ for Vitamin B₁₂ Deficiency

Cochrane DB Syst Rev 2005;3:CD004655

**Study**: Systematic review. 2 RCTs met inclusion criteria, total 108 patients with follow-up from 90 d-4 mo.

**Intervention**: One study evaluated 1000 µg of oral B₁₂ compared to 1000 µg IM B₁₂ on the same dosing schedule. The other compared 2000 µg daily oral B₁₂ to 1000 µg IM B₁₂ on a less frequent dosing schedule. Neurological and hematological end points were evaluated.

**Results**: Meta-analysis was not attempted due to study heterogeneity. Both studies reported improvements in hematological and neurological end-points in both oral and IM groups. No significant difference was observed between groups in either study.

**Conclusions**: Limited data suggests high dose oral vitamin B₁₂ (1000-2000 µg) is equivalent to IM vitamin B₁₂ on the same or less frequent dosing schedule. This data is limited by small sample sizes and short follow-up periods. However, it suggests that a 3 to 4 mo trial of oral supplementation is a reasonable first choice for patients with B₁₂ deficiency.

Schilling Test

**Part 1**

- Tracer dose (1 µg) of radiolabeled B₁₂ given PO
- Flushing dose (1 mg) of unlabeled B₁₂ IM 1 h later to saturate tissue binders of B₁₂ thus allowing radioactive B₁₂ to be excreted in urine
- 24 h urine radiolabeled B₁₂ measured
- Normal >5% excretion (a normal excretion will only be seen if the low B₁₂ was due to dietary deficiency)

**Part 2**

- Same as part 1, but radiolabeled B₁₂ given with oral intrinsic factor
- Should be done only if first stage shows reduced excretion
- Normal test result (>5% excretion) = pernicious anemia
- Abnormal test result (<5% excretion) = intestinal causes (malabsorption)
**Folate Deficiency**

- uncommon in developed countries due to extensive dietary supplementation (enriched in flour)
- folate stores are depleted in 3-6 mo
- folate commonly found in green, leafy vegetables and fortified cereals

**Etiology**

**Table 17. Etiology of Folate Deficiency**

<table>
<thead>
<tr>
<th>Diet/Deficiency</th>

<td>Hemodialysis</td>
</tr>
</tbody>
</table>

**Clinical Features**

- anemia, mild jaundice, glossitis, diarrhea, confusion, pallor
- consider social history, alcohol/drug abuse, very poor diet (e.g. elderly, depressed)

**Investigations**

- similar to B12 deficiency (CBC, reticulocytes, blood film, RBC folate, and serum B12)
- if decreased RBC folate, rule out B12 deficiency as cause

**Management**

- folic acid 1-5 mg PO OD x 1-4 mo; then 1 mg PO OD maintenance if cause is not reversible

**Hemostasis**

**Stages of Hemostasis**

1. **Primary Hemostasis**
   - cellular defense – involves the platelet and vWF predominantly
   - goal is rapid cessation of bleeding; main effect is on mucocutaneous bleeding
   - vessel injury results in collagen/subendothelial matrix exposure and release of vasoconstrictors
   - blood flow is impeded and platelets come into contact with damaged vessel wall (Figure 12a, H26)
     - activation: platelets are activated resulting in change of shape and release of adenosine diphosphate (ADP) and thromboxane A2
     - adhesion: platelets adhere to subendothelium via von Willebrand factor (vWF)
     - aggregation: these factors further recruit and aggregate more platelets resulting in formation of localized hemostatic plug

2. **Secondary Hemostasis**
   - platelet plug is reinforced by production of fibrin clot (Figure 12b, H26)
   - extrinsic (initiation) pathway: initiation of coagulation in vivo
   - intrinsic (amplification) pathway: amplification once coagulation has started via positive feedback
   - both intrinsic and extrinsic pathways converge onto the common pathway which results in thrombin generation and fibrin formation

3. **Fibrin Stabilization**
   - conversion from soluble to insoluble and stable clot

4. **Fibrinolysis**
   - once healing initiated, clot dissolution via action of the fibrinolytic system
**Hemostasis**

**Commonly Used Tests of Hemostasis**

**Tests of Secondary Hemostasis**

*PT/INR: Tennis is played outside (Extrinsic pathway)*

*PTT: Table Tennis is played inside (Intrinsic pathway)*

**Figure 12a. Platelet activation cascade**

**Figure 12b. Coagulation cascade**

**Figure 13. Clotting factors involved in PT and PTT**

**Tests of Prolonged PTT Without Bleeding include:**
1. Early contact factor (Factor XII, HMWK, PK) deficiency
2. Lupus anticoagulant
3. Inappropriate blood draw
4. Heparin contamination
5. Erythrocytosis (laboratory artifact)

**Consider PTT**
- IV heparin, argatroban monitoring
- Hemophilia A/B, factor XI deficiency, severe vWF
Disorders of Primary Hemostasis

Definition
- inability to form an adequate platelet plug due to:
  - disorders of blood vessels
  - disorders of platelets: abnormal function/numbers
  - disorders of vWF

Terminology of ITP
- also known as immune thrombocytopenia
- primary: isolated thrombocytopenia (platelet count <100 x 10⁹/L) with no other cause of thrombocytopenia
- secondary: thrombocytopenia associated with another condition (e.g. HIV, HCV, SLE, CLL)
- drug-induced: drug-dependent platelet antibodies causing platelet destruction
Classification of Primary ITP
- acute: newly diagnosed (diagnosis to 3 mo)
- persistent: 3-12 mo from diagnosis
- chronic: >12 mo
- refractory: post-splenectomy

Pathophysiology
- primary or secondary ITP
- an acquired immune-mediated disorder (pathophysiology incompletely understood)
  - anti-platelet antibodies bind to platelet surface → increased splenic clearance
  - impaired platelet production
  - helper T-cell and cytotoxic T-cell activation also implicated in platelet destruction

Clinical Feature
- variable presentation: asymptomatic, fatigue, minimal bruising, mucocutaneous bleed (e.g. purpura, ecchymoses, petechiae, continuous epistaxis, menorrhagia), and intracranial bleed
- assess for symptoms/signs suggesting a secondary cause

Investigations
- CBC and reticulocyte count: thrombocytopenia
- PT and aPTT: normal
- peripheral blood film: decreased platelets, giant platelets (rule out platelet clumping)
- HIV, HCV, H. pylori serology
- vitamin B12, ANA, C3, C4, depending on clinical symptoms
- bone marrow aspirate and biopsy: increased number of megakaryocytes
  - recommended in patients >60 yr of age, pre-splenectomy or have failed traditional ITP therapy, those with systemic symptoms, an abnormal blood film
- bone marrow aspirate and biopsy should be considered if there is any suspicion of diminished bone marrow function (e.g. myelodysplasia, infiltration)

Treatment
- rarely indicated if platelets >30 x 10⁹/L unless active bleeding, trauma, or surgery
- emergency treatment (active bleeding [CNS, GI, or GU] or in need of emergency surgery)
  - general measures: stop drugs that reduce platelet function, control blood pressure, minimize trauma
  - corticosteroids: prednisone (1 mg/kg/d) or dexamethasone (40 mg PO/d x 4 d)
  - antifibrinolytic: tranexamic acid (1 g PO tid or 1 g IV q6h) if mucosal bleeding
  - IVig 1 g/kg/d x 2 doses (raises platelet count faster than corticosteroids)
  - platelet transfusion: for refractory, major bleeding or need for urgent surgery (expect that platelet recovery will be diminished)
  - emergency splenectomy: may be considered, vaccinations prior if possible (pneumococcus, meningococcus, H. influenzae b)
  - management of intracranial bleeding: IV steroids, IVlg, platelets
- non-urgent treatment (platelet count <20-30 x 10⁹/L and no bleeding)
  - 1st-line
    - corticosteroids (dexamethasone 40 mg PO qd x 4 d x 1-4 cycles (not wk) or prednisone x 3 wk then slow taper)
    - IVig
    - anti-D: appropriate for Rh+ non-splenectomized patients, but can cause hemolysis (avoid if low Hb at baseline or if DAT is positive)
  - 2nd-line
    - splenectomy (need vaccinations prior to splenectomy: pneumococcus, meningococcus, and H. influenzae b)
    - rituximab
  - 3rd-line
    - thrombopoietin (TPO) receptor agonists (romiplostim, eltrombopag) – may be considered for 2nd-line therapy if funding available
    - immunomodulating therapy (azathioprine, cyclophosphamide, danazol, and vincristine)

Definitions of Response to Treatment
- complete response: platelet >100
- partial response: platelet 30-100
- no response: platelet <30

Prognosis
- ~20% will not attain a hemostatic platelet count after first and second line therapy
- fluctuating course
- overall relatively benign, life-expectancy similar to general population (however, risk of mortality from bleeding/infection increases with advancing age)
- major concern is spontaneous intracranial hemorrhage if platelet <5 x 10⁹/L, more common in the elderly
Table 22. Heparin-Induced Thrombocytopenia (HIT)

<table>
<thead>
<tr>
<th>Pathophysiology</th>
<th>Immune mediated Ab recognizes a complex of heparin and platelet factor 4 (PF4) leading to platelet activation via platelet Fc receptor and activation of coagulation system</th>
</tr>

</tbody>
</table>

Note: atypical HUS is a complex disease with different etiology, treatment depends on genetic abnormalities

von Willebrand Disease

**Pathophysiology**
- most common inherited bleeding disorder (prevalence of 1%)
- usually autosomal dominant (type 3 is autosomal recessive)
- women more commonly diagnosed (heavy menstrual bleeding, peripartum bleeding)
- qualitative defect or quantitative deficiency of vWF depending on type
  - vWF needed for platelet adhesion/aggregation and acts as chaperone for Factor VIII (extending its half-life in circulation), therefore abnormality of vWF can affect both primary and secondary hemostasis
  - vWF exists as a series of multimers ranging in size
    - largest multimers are most active in mediation of platelet adhesion/aggregation
    - both large and small multimers complex with Factor VIII
  - vWF levels vary according to blood group (non-group O patients have higher levels than group O patients)

**Classification**
- type 1: mild quantitative defect (decreased amount of vWF and proportional decrease in vWF activity) ~ 80% of cases
- type 2: qualitative defect (vWF activity disproportionally lower than quantity) ~ 20% of cases
- type 3: severe total quantitative defect (virtually no vWF produced) ~ 1 per million

**Clinical Features**
- bleeding history is the single most important predictor of an underlying bleeding disorder
- validated, standardized bleeding assessment tools (e.g. ISTH-BAT) to facilitate exploration of the bleeding history
- mucocutaneous bleeding (easy bruising, epistaxis (>10 min), heavy menstrual bleeding, peripartum bleeding, post-dental extraction bleeding, excessive post-operative bleeding, and unexplained gastrointestinal bleeding)
  - type 3 vWF patients can experience musculoskeletal bleeding due to significant deficiency in FVIII due to lack of FVIII chaperoning as vWF is absent
  - family history of a bleeding disorder

**Investigations**
- CBC, platelet, vWF:Antigen (determine how much vWF is present), vWF:Ristocetin cofactor activity (determine how well vWF binds to platelet), Factor VIII (determine how well vWF chaperones with FVIII), and PTT
- tests to further categorize type/subtype of vWD: multimer analysis, ristocetin induced platelet agglutination, and genetic studies
Disorders of Secondary Hemostasis

**Treatment**
- desmopressin (DDAVP®) is effective treatment for 85-90% of patients with type 1 vWD and for some subtypes of type 2 vWD
  - causes release of vWF and Factor VIII from endothelial cells
  - variable efficacy depending on disease type: tachyphylaxis occurs after 4 consecutive doses
  - need to document responsiveness with ‘DDAVP® challenge’
  - caution in children due to hyponatremia
- tranexamic acid (Cyklokapron®, anti-fibrinolytic) to stabilize clot formation
- vWF:FVIII concentrate (Humate P®, Wilate®) if DDAVP® unresponsive/clinically ineffective or for severe bleeding episode
  - need to monitor vWF and factor VIII levels (very high factor VIII level can be prothrombotic)
- gynecologic focused care for heavy menstrual bleeding (NB estrogens have the added benefit of increasing vWF levels)

**Prognosis**
- patients with mild type 1 vWD have auto-correction of vWF deficiency in pregnancy
- most cases are mild-moderate, and only ~10% of cases require long-term prophylactic therapy

**Disorders of Secondary Hemostasis**

**Definition**
- inability to form an adequate fibrin clot
  - disorders of clotting factors or co-factors
  - disorders of proteins associated with fibrinolysis
- characterized by delayed bleeding, deep muscular bleeding, and spontaneous hemarthroses

**Table 26. Classification of Secondary Hemostasis Disorders**

</tr>
</tbody>
</table>

**Hemophilia A (Factor VIII Deficiency)**

**Pathophysiology**
- X-linked recessive, 1/5000 males
- mild (>5% of normal factor level), moderate (1-5%), severe (<1%)

**Clinical Features**
- see Table 19 – Signs and Symptoms of Disorders of Hemostasis, H26
- older patients may also acquired HIV or HCV from contaminated blood products

**Investigations**
- prolonged aPTT, normal INR (PT)
- decreased Factor VIII (<40% of normal)

**Treatment**
- desmopressin (DDAVP®) in mild hemophilia A
- Factor VIII concentrate for:
  - prophylaxis
  - on-demand (i.e. to treat a bleed)
- anti-fibrinolytic agents (e.g. tranexamic acid)

**Hemophilia B (Factor IX Deficiency)**

- X-linked recessive, 1/30,000 males; approximately half have severe disease (factor IX activity <1% of normal)
- clinical and laboratory features identical to hemophilia A (except decreased Factor IX)
- treatment: Factor IX concentrate (prophylaxis or on-demand), anti-fibrinolytic agents
Factor XI Deficiency

- autosomal recessive; more common in Ashkenazi Jewish population
- usually mild, often diagnosed in adulthood
- Factor XI level does not correlate with bleeding risk – risk of bleeding correlates with a previous history or family history of bleeding
- treatment: antifibrinolytic agents, frozen plasma, and Factor XI concentrate

Liver Disease

- see Gastroenterology, G31

Pathophysiology

- deficient synthesis of all factors except VIII (also made in endothelium)
- aberrant or diminished synthesis of fibrinogen (factor I)
- diminished synthesis of natural anticoagulants and altered regulation of fibrinolysis

Investigations

- peripheral blood film: target cells
- primary hemostasis affected
  - thrombocytopenia 2º to hypersplenism, nutritional deficiency, direct bone marrow toxicity related to alcohol, diminished production from chronic viral infections (e.g. HCV), and decreased production of thrombopoietin
- secondary hemostasis affected
  - elevated INR (PT), aPTT, TT (thrombin time)
  - low fibrinogen in end-stage liver disease

Treatment

- supportive, treat liver disease, blood products if active bleeding (frozen plasma, platelets, cryoprecipitate)

Vitamin K Deficiency

Etiology

- drugs
  - vitamin K antagonist (e.g. Warfarin) – diminished production of functional Factors II, VII, IX, X, proteins C and S
  - antibiotics eradicating gut flora, altering vitamin K uptake
- poor diet (especially in alcoholics) e.g. prolonged fasting or starvation
- biliary obstruction
- chronic liver disease (decreased stores)
- fat malabsorption (e.g. celiac disease, disorders of bile or pancreatic secretion, and intestinal disease, CF)
- hemorrhagic disease of newborn, see Pediatrics, P64

Investigations

- INR (PT) is elevated out of proportion to elevation of the aPTT
- decreased Factors II, VII, IX, X (vitamin K-dependent)

Treatment

- hold anticoagulant if vitamin K antagonist on board
- vitamin K PO if no active bleeding
- if bleeding, give vitamin K 10 mg IV (reversal may take up to 12 h)
- if life-threatening bleeding and vitamin K antagonist used, give prothrombin complex concentrate (PCC) or FP if PCC contraindicated
- PCCs are contraindicated in liver disease and if there is a previous history of HIT (PCC product contains heparin)

Disseminated Intravascular Coagulation

Definition

- excessive, dysregulated release of plasmin and thrombin leading to intravascular coagulation and depletion of platelets, coagulation factors and fibrinogen
- risk of life-threatening hemorrhage or thromboembolism

Etiology

- occurs as a complication of many other severe medical, surgical or obstetrical conditions
- widespread endothelial damage and extensive inflammatory cytokine release
**Hypercoagulable Disorders**

**Hypercoagulability Workup – Venous Thrombosis**
- workup for hypercoagulable state is controversial and should only be done if it will alter treatment decisions
  - recommendations for a hypercoagulable workup include:
    - patients with recurrent or multiple thrombosis only if it will change management plans
    - warfarin-induced skin necrosis or neonatal purpura fulminans (protein C or S deficiency)
    - consider for patients with a family history of VTE who are considering OCP use
    - consider for patients who present with thrombosis at an unusual venous site only if it will change management plans
    - workup for malignancy is suggested in the event of abnormal blood work, constitutional symptoms or physical exam suggestive of cancer
    - arterial thrombotic events due to a hypercoagulable state are typically associated with APLA, HIT, JAK2 MPNs, and PNH, not hereditary thrombophilias

<td></td>
</tr>
</tbody>
</table>

**Investigations**
- primary hemostasis: decreased platelets
- secondary hemostasis: prolonged INR (PT), aPTT, TT, decreased fibrinogen and other factors
- fibrinolysis: increased FDPs or D-dimers and short euglobulin lysis time (i.e. accelerated fibrinolysis)
- extent of fibrin deposition: urine output and RBC fragmentation

**Treatment**
- recognize early and treat underlying disorder – supportive measures: hemodynamic and/or ventilator support, aggressive hydration, and RBC transfusion if severe bleed
- in hemorrhage: replacement of hemostatic elements with platelet transfusion, frozen plasma, and cryoprecipitate
  - British Hematology Guidelines:
    - maintain platelets >50 x 10⁹/L, hemoglobin >80 g/L, calcium between 2.2-2.7 mmol/L, and avoid hypothermia
    - 4-5 units of FP if INR >1.5 or aPTT >38
    - 10 units of cryoprecipitate if fibrinogen <1 g/L
    - 1 adult dose ofuffy-coat platelets if <10 x 10⁹/L (<20 if febrile, <50 before invasive procedure)
- in thrombotic phase: UFH or LMWH in critically ill, non-bleeding patients

**Hypercoagulable Disorders**

**American Society of Hematology Choosing Wisely Recommendations**
1. Do not test for thrombophilia in adult patients with venous thromboembolism occurring in the setting of major transient risk factors (surgery, trauma, or prolonged immobility)
2. Do not use inferior vena cava filters routinely in patients with acute venous thromboembolism
**SELECTED CAUSES OF HYPERCOAGULABILITY**

**Activated Protein C Resistance (Factor V Leiden)**
- most common cause of hereditary thrombophilia
- 3-7% of European Caucasian population are heterozygotes
- point mutation in the Factor V gene (R506Q) results in resistance to inactivation of Factor Va by activated protein C

**Prothrombin Gene Mutation (PT) G20210A**
- 1-3% of European Caucasian population are heterozygotes
- G to A transposition at nucleotide position 20210 of the prothrombin gene promoter region results in increased levels of prothrombin, thus increased thrombin generation

**Protein C and Protein S Deficiency**
- protein C inactivates Factor Va and VIIa using protein S as a cofactor
- protein C deficiency
  - homozygous or compound heterozygous: neonatal purpura fulminans
  - type I: decreased protein C levels
  - type II: decreased protein C activity
- acquired: liver disease, sepsis, DIC, warfarin, and certain chemotherapeutic agents
- 1/3 of patients with warfarin necrosis have underlying protein C deficiency
- protein S deficiency
  - type I: decreased free and total protein S levels
  - type II: decreased protein S activity
  - type III: decreased free protein S levels
  - acquired: liver disease, DIC, pregnancy, nephrotic syndrome, inflammatory conditions, and warfarin

**Antithrombin Deficiency**
- antithrombin slowly inactivates thrombin in the absence of heparin, rapidly inactivates thrombin in the presence of heparin
- autosomal dominant inheritance, urinary losses in nephrotic syndrome, or reduced synthesis in liver disease
- diagnosis must be made outside window of acute thrombosis and anticoagulation treatment (acute thrombosis, heparin, systemic disease all decrease antithrombin levels)
- deficiency may result in resistance to unfractionated heparin (LMWH may be considered, with monitoring of anti-Xa levels)
  - heparin resistance: suspect if >35,000 units of UFH required during 24 h use

**Elevated Factor VIII Levels**
- an independent marker of increased incident and recurrent thrombotic risk, but levels can also be increased in numerous states as an acute phase reactant, therefore its clinical use is controversial

**Congenital Dysfibrinogenemia**
- may predispose to thromboembolic disease, bleeding or both

**Disorders of Fibrinolysis**
- includes congenital plasminogen deficiency, tissue plasminogen activator deficiency, although association with VTE risk is not clear

**Antiphospholipid Antibody Syndrome (APS)**
- definition: ≥1 clinical and ≥1 laboratory criteria
  - clinical: arterial or venous thrombosis, recurrent (>3) early pregnancy losses <10 wk, one late fetal loss ≥10 wk (morphologically normal), or premature birth before 34 wk due to (pre)eclampsia or placental insufficiency
  - laboratory (must be confirmed on two occasions, tested ≥12 wk apart): anticardiolipin antibodies, anti-β2 glycoprotein-I antibody, or lupus anticoagulant
- mechanism: not well understood, antibodies interact with platelet membrane phospholipid causing increased activation; can also interfere with thrombin regulation, fibrinolysis, and inhibit the protein C pathway
  - see Rheumatology, RH13
Venous Thromboembolism

Definition
- thrombus formation and subsequent inflammatory response in a superficial or deep vein
- superficial thrombophlebitis, deep vein thrombosis (DVT), and pulmonary embolism (PE)
- thrombi propagate in the direction of blood flow (commonly originating in calf veins)
- more common in lower extremity than upper extremity
- incidence ~1% if age >60 yr
- most important sequelae are pulmonary embolism (~50% chance with proximal DVT) and chronic venous insufficiency

Etiology (Virchow’s Triad)
- endothelial damage
  - exposes endothelium to prompt hemostasis
  - leads to decreased inhibition of coagulation and local fibrinolysis
- venous stasis
  - immobilization (post-MI, CHF, stroke, and post-operative) inhibits clearance and dilution of coagulation factors
- hypercoagulability
  - inherited (see Hypercoagulable Disorders, H33)
  - acquired
    - age (risk increases with age)
    - surgery (especially orthopedic, thoracic, GI, and GU)
    - trauma (especially fractures of spine, pelvis, femur or tibia, and spinal cord injury)
    - neoplasms (especially lung, pancreas, colon, rectum, kidney, and prostate)
    - blood dyscrasias (myeloproliferative neoplasms, especially PV, ET), PNH, and hyperviscosity
      (multiple myeloma, polycythemia, leukemia, and sickle cell disease)
    - prolonged immobilization (CHF, stroke, MI, and leg injury)
    - hormone related (OCP, HRT, and SERMs)
    - pregnancy
    - APS
    - heart failure (risk of DVT greatest with right heart failure and peripheral edema)
  - idiopathic (10-20% are later found to have cancer)

Clinical Features of DVT
- absence of physical findings does not rule out disease
- unilateral leg edema, erythema, warmth, and tenderness; purple-blue colour
- palpable cord (thrombosed vein)
- phlebismas alba dolens (white appearance) and phlebismas cerula dolens (acute pain and edema) with massive thrombosis
- Homan’s sign (pain with foot dorsiflexion) is unreliable

Differential Diagnosis of DVT
- muscle strain or tear, lymphangitis or lymph obstruction, venous valvular insufficiency, ruptured popliteal cysts, cellulitis, and arterial occlusive disease

Investigations for DVT
- D-dimer test only useful to rule out DVT if negative with low clinical suspicion of disease and no other acute medical issues
- doppler ultrasound is most useful diagnostic test for DVT
  - sensitivity and specificity for proximal DVT ~95%
  - sensitivity for calf DVT ~70%
- other non-invasive tests include MRI and impedance plethysmography
- venography is the gold standard, but is expensive, invasive, and of higher risk
- CTPA or V/Q scan if PE suspected

Post-Thrombotic Syndrome
- development of chronic venous stasis signs and symptoms secondary to a deep venous thrombosis
- symptoms: pain, venous dilatation, edema, pigmentation, skin changes, and venous ulcers
- clinical severity can be estimated based on the Villalta score
- large impact on quality of life following a DVT
- treatment: extremity elevation, exercise, continuous compression stockings, intermittent pneumatic compression therapy, and skin/ulcer care
- for clinical features and treatment of PE, see Respirology, R19

Wells’ Score for DVT Criteria (Score)

<table>
<thead>
<tr>
<th>Score</th>
<th>Criteria</th>
</tr>
</thead>
<tbody>
<tr>
<td>Low probability</td>
<td>0-2</td>
</tr>
<tr>
<td>Moderate probability</td>
<td>3-5</td>
</tr>
<tr>
<td>High probability</td>
<td>6-8</td>
</tr>
</tbody>
</table>

Wells’ Score for DVT

- Paralysis, paresis, or recent orthopedic casting of lower extremity (7)
- Recently bedridden (3-5) or major surgery within past 4 wk (0)
- Localized tenderness in deep vein system (1)
- Swelling of entire leg (1)
- Calf swelling >2 cm than other leg (measured 10 cm below the tibial tuberosity) (1)
- Phlebismas alba dolens (white appearance) and phlebismas cerula dolens (acute pain and edema) with massive thrombosis (2)
- Homan’s sign (pain with foot dorsiflexion) is unreliable (3)

Modifed Wells Score

Same as above except with an additional point for a history of DVT or major surgery within past 12 wk, and the score interpretation is DVT likely for ≥ 2 points and DVT unlikely for ≤ 1 point. D-dimer is ordered for DVT unlikely patients to fully rule out DVT which can help reduce unnecessary ultrasounds

Low-Molecular-Weight Heparin vs. Coumadin® for the Prevention of Recurrent Venous Thromboembolism in Patients with Cancer

Study: RCT comparing the efficacy of LMWH (dalteparin) with an oral anti-coagulant agent (coumadin) in preventing recurrent thrombosis in patients with cancer.

Methods: Patients with cancer who had acute, symptomatic proximal DVT, PE, or both were randomly assigned to either dalteparin or coumadin treatment for 6 mo.

Results: 27 of 228 patients in the dalteparin group had recurrent VTE versus 53 of 336 patients in the coumadin group (hazard ratio, 1.48; p=0.012). The probability of recurrent thromboembolism at 6 mo was 8% and 11% in the dalteparin and coumadin groups respectively. There was no significant difference in bleeding rates. The mortality rate was 35% in the dalteparin group and 41% in the coumadin group.

Conclusions: In patients with cancer and acute VTE, dalteparin was more effective than coumadin in decreasing the risk of recurrent thromboembolism without increasing the risk of bleeding.
**Approach to Treatment of Venous Thromboembolism**

### Purpose
- Prevent further clot extension (3 mo duration is optimal)
- Prevent acute pulmonary embolism (occurs in up to 50% of untreated patients)
- Reduce the risk of recurrent thrombosis (duration depends on presence of other risk factors)
- Treatment of massive iliofemoral thrombosis with acute lower limb ischemia and/or venous gangrene (phlegmasia cerulea dolens)
- Limit development of late complications (e.g., postphlebitic syndrome, chronic venous insufficiency, and chronic thromboembolic pulmonary HTN)

### Initial Treatment
- Low molecular weight heparin (LMWH)
  - Administered SC, at least as effective as UFH with a lower bleeding risk
  - Advantages: predictable dose response and fixed dosing schedule; lab monitoring not required; <1% HIT; safe and effective outpatient therapy
  - Disadvantages: only partially reversible by protamine, long-term use associated with osteoporosis, costly
  - Renally cleared – must adjust dose in patients with renal dysfunction
- Unfractionated heparin (UFH)
  - In patient with average risk of bleed; use hospital-based nomograms that use bleeding risk and patient weight to determine appropriate dose
  - Advantages: rapidly reversible by protamine
  - Disadvantages: must monitor aPTT or heparin levels with adjustment of dose to reach therapeutic level (~2x normal value); monitor platelet counts for development of HIT
- Alternatives to LMWH and UFH
  - Direct thrombin inhibitors (hirudin, lepirudin, argatroban) and direct factor Xa inhibitors (apixaban, rivaroxaban)
  - Thrombolytic drugs (e.g., streptokinase, tPA) reserved for acute limb/life-threatening thrombosis, and low bleeding risk

### Long-Term Treatment
- Anticoagulation therapy
  - Warfarin
    - Standard treatment; should be initiated with heparin overlap; dual therapy for at least 48 hours with INR >2, due to initial prothrombotic state secondary to warfarin's inhibition of natural anticoagulants protein C/S, half-life of vitamin K factors and risk of warfarin-induced skin necrosis
    - INR: warfarin dosed to maintain INR at 2-3, monitor twice weekly for 1-2 wk
      - Discontinue heparin after INR>2.0 for 2 consecutive days
  - Direct oral anticoagulants (DOACs)
    - Apixaban or rivaroxaban; with no laboratory monitoring required, patients with CrCl >25 mL/min (apixaban) or 30 mL/min (rivaroxaban)
    - Dabigatran (factor IIa inhibitor): LMWH or IV heparin for at least 5-10 d before initiating dabigatran, patients with CrCl >30 mL/min
    - Important drug interactions to consider for DOACs (no relevant food interactions however)
    - Cancer patients: LMWH more effective than warfarin at preventing recurrence of venous thrombosis in cancer patients; increasing evidence to support DOACs in cancer-associated thrombosis
- Duration of anticoagulant treatment
  - Provoked VTE with transient risk factor: 3 mo
  - Provoked VTE with ongoing risk factor: consider indefinite therapy with annual reassessment
  - First unprovoked VTE: at least 3 mo, subsequent reassessment
  - Unprovoked proximal DVT or PE: consider indefinite therapy with annual reassessment
  - Second unprovoked VTE: consider indefinite therapy
  - Cancer-associated DVT: at least 3 mo, longer if continued evidence of cancer
- IVC filters
  - Temporary filter indicated only if acute DVT (<4 wk) with significant contraindications to anticoagulant therapy (i.e., active bleeding) or if require interruption of anticoagulation (i.e., for urgent surgery)
  - Must be retrieved once safe to do so as filter is pro-thrombotic in the long-term (consider anticoagulation if not retrieved)
- Special considerations
  - Pregnancy: treat with LMWH during pregnancy, then LMWH or warfarin for 6 wk post-partum (minimum total anticoagulation time of 3-6 mo, but must include 6 wk post-partum, as this is a high risk period); avoid warfarin in pregnancy due to teratogenicity, avoid DOAC in pregnancy (due to lack of data) and if breastfeeding in postpartum period
• surgery: avoid elective surgery in the first 3 mo after a venous thromboembolic event
  • pre-operatively: IV heparin may be used up to 4–6 h pre-operatively
  • perioperatively: warfarin or DOACs discontinued for at least 3–5 d pre-operatively (consider mechanism of drug clearance)
  • post-operatively: IV heparin, LMWH, DOAC can be used for anticoagulation (consult with surgeon prior to re-initiation)
  • for patients at high risk for thromboembolism (VTE <12 wk, recurrent VTE, antiphospholipid antibody syndrome, atrial fibrillation with prior stroke, and mechanical heart valve), IV heparin or LMWH (bridging) should be considered before and after the procedure while the INR is below 2.0

Prophylaxis
• consider for those with a moderate to high risk of thrombosis without contraindications
• non-pharmacological measures include: early ambulation, elastic compression stockings (TEDs), and intermittent pneumatic compression (IPC)
• UFH 5000 IU SC bid, UFH 5000 IU SC tid or LMWH as per hospital protocol (e.g. enoxaparin 40 mg SC daily, dalteparin 5000 U SC qid), and DOACs for orthopedic surgery thromboprophylaxis

Hematologic Malignancies and Related Disorders

Figure 15. Hematopoietic derivation of hematologic disorders

Acute Leukemia
Definition (WHO): presence of 20% blast cells or greater in the peripheral blood or bone marrow at presentation
Classification: divided into myeloid (AML) and lymphoid (ALL) depending on whether blasts are myeloblasts or lymphoblasts, respectively

Auer rods are pathognomonic for AML

Basic initial workup for all hematological malignancies:
1. ALL CHILDBEARING WOMEN must have a b-HCG pre initiation of treatment of any cancer diagnosis
2. ALL PATIENTS MUST HAVE HBsAb, HBsAg, HBcAb collected irrespective of cancer diagnosis and must be treated to avoid reactivation
3. All aggressive lymphoma patients must be screened for HIV
4. All patients must be screened for TB risk factors
Myeloid Malignancies

Acute Myeloid Leukemia

Definition
- rapidly progressive malignancy characterized by failure of myeloid cells to differentiate beyond blast stage

Epidemiology
- incidence increases with age; median age of onset is 65 yr old; 80% of acute adult leukemias
- accounts for 10-15% of childhood leukemias

Risk Factors
- male, older age, smoking, obesity, myelodysplastic syndromes (MDS), benzene, radiation, Down Syndrome, alkylating agents and radiation therapy as treatment for previous malignancy

Pathophysiology
- etiology subdivided into:
  - primary: de novo
  - secondary: hematologic malignancies (e.g. myeloproliferative disorders and MDS) or previous chemotherapeutic agents (e.g. alkylating agents)
- uncontrolled growth of blasts in marrow leads to:
  - suppression of normal hematopoietic cells
  - appearance of blasts in peripheral blood – risk of leukostasis
  - accumulation of blasts in other sites (e.g. skin, gums)
  - metabolic consequences; tumour lysis syndrome

Clinical Features
- signs and symptoms develop over a period of weeks
- manifestations of bone marrow failure
  - anemia, thrombocytopenia (associated with DIC in promyelocytic leukemia), neutropenia (even with normal WBC), leads to infections, and fever
- accumulation of blast cells in marrow
  - skeletal pain, bony tenderness (especially sternum)
- organ infiltration
  - gingival hypertrophy (particularly myelomonocytic leukemia) – may present to dentist first
  - extramedullary involvement
  - hepatosplenomegaly (in ALL)
  - lymphadenopathy (not marked in ALL)
  - gonads (in ALL)
  - skin: leukemia cutis or myeloid sarcoma
  - eyes: hemorrhages and/or whitish plaques, Roth spots, cotton wool spots, and vision changes (uncommon)
- leukostasis/hyperleukocytosis syndrome (medical emergency)
  - large numbers of blasts interfere with circulation and lead to hypoxia and hemorrhage – can cause diffuse pulmonary infiltrates, CNS bleeding, respiratory distress, altered mental status, and priapism
  - associated with AML more than ALL
- metabolic effects; aggravated by treatment
  - increased uric acid → nephropathy, gout
  - release of phosphate → decreased Ca²⁺, decreased Mg²⁺
  - release of procoagulants → DIC (higher risk in acute promyelocytic leukemia)
- tumour lysis syndrome
  - hyperkalemia pre-treatment from blastic proliferation K⁺ after treatment (from lysed cells). Note – some forms of AML can present with hypokalemia due to secreted muraimdase that causes K⁺ wasting from renal tubules
Investigations

- blood work
  - CBC: anemia, thrombocytopenia, variable WBC (most often cytopenias + blasts)
  - INR, aPTT, fibrin degradation products (FDP), fibrinogen (in case of DIC)
  - increased LDH, increased uric acid, increased PO₄²⁻ (released by leukemic blasts), decreased Ca²⁺, in/decreased K⁺
  - baseline renal and liver function tests
  - if considering treatment: screen for HepB, HepC, HIV, CMV
- peripheral blood film – circulating blasts with Auer rods (azurophilic granules) are pathognomonic for AML
- bone marrow aspirate for definitive diagnosis
  - blast count: AML >20% (normal is <5%)
  - morphologic, cytochemical, and/or immunophenotypic features are used to establish lineage and maturation
- CXR to rule out pneumonia; ECG, MUGA scan prior to chemotherapy (cardiotoxic)

Treatment

- mainstay of treatment is chemotherapy (rapidly fatal without treatment)
- all AML subtypes are treated similarly, except acute promyelocytic leukemia (APL) with t(15:17) translocation

  1. Induction: chemotherapy to induce complete remission of AML
     - several possible regimens
     - patients with Poor response to initial induction therapy – worse prognosis
     - must ensure reversal of DIC, platelet transfusions if <10
  2. Consolidation: to prevent recurrence
     - intensive consolidation chemotherapy
     - stem cell transplantation – allogeneic (younger patients with better performance status)

- supportive care
  - fever, C&S of all orifices, CXR, and start antibiotics
  - platelet and RBC transfusions ± EPO
  - prevention and treatment of metabolic abnormalities
    - allopurinol, rasburicase for prevention of hyperuricemia
  - leukostasis
    - needs immediate cytoreductive therapy (i.e. hydroxyurea)
  - treatment strategy for APL
    - APL is an emergency as DIC is often presented at diagnosis
    - all-trans-retinoic acid (ATRA) added to induce differentiation; arsenic trioxide and ATRA combination therapy for APL is non-inferior to traditional chemotherapy

Prognosis

- achievement of first remission
  - 70-80% if ≤60 yr old, 50% if >60 yr old
  - median survival 12-24 mo
  - prognosis is most related to 1) cytogenetics; classified as favourable, intermediate, or adverse and 2) molecular studies (i.e. NPM1+/FLT3- mutations)
  - prognosis depends on cytogenetics, age, performance status, prior cytotoxic agents, or radiation therapy

Myelodysplastic Syndromes

Definition

- heterogeneous group of malignant stem cell disorders characterized by dysplastic and ineffective blood cell production resulting in peripheral cytopenias, and a variable risk of transformation to acute leukemias
- syndromes defined according to World Health Organization (WHO) classifications

Pathophysiology

- disordered maturation: ineffective hematopoiesis despite presence of adequate numbers of progenitor cells in bone marrow (usually hypercellular); formed elements sometimes exhibit morphological and functional defects
- intramedullary apoptosis: programmed cell death within bone marrow
- both processes lead to reduced mature cells in periphery
- <30% develop AML

Risk Factors

- elderly, post-chemotherapy, exposures (benzene, tobacco, radiation), inherited genetic abnormalities
- incidence: 50 persons per million per year, rises to 200–400 per million per year for age 70 or older

Clinical Features

- highly variable, commonly presents with symptoms of anemia (fatigue and dyspnea), thrombocytopenia (bruising, bleeding or petechiae), and neutropenia (recurrent infections) over months-years
Myeloproliferative Neoplasms

Investigations
- diagnosed by:
  - anemia ± thrombocytopenia ± neutropenia
  - CBC and peripheral blood film
  - RBC: usually macrocytic with oval shaped red cells (macro-ovalocytes), decreased reticulocyte count
  - WBC: decreased granulocytes and abnormal morphology (e.g. bi-lobed or unsegmented nuclei = Pelger abnormality)
  - platelets: thrombocytopenia, abnormalities of size, and cytoplasm (e.g. giant hypogranular platelets)
- bone marrow aspirate and biopsy with cytogenetic analysis required for definitive diagnosis
  - bone marrow: dysplastic and often normocellular/hypercellular
  - cytogenetics: high risk (partial or total loss of chromosome 7) and complex (>3 abnormalities)

Treatment
- low risk of transformation to acute leukemia (IPSS-R Very Low or Low)
  - erythropoietin stimulating agents weekly is first line in reducing transfusion requirements (EPO level must be <500)
  - hypomethylating agents: decitabine and azacitidine
  - if 5q deletion based on cytogenetics: lenalidomide PO
  - supportive care: RBC and platelet transfusion (consider iron chelation if frequent RBC transfusions)
- high risk of transformation to acute leukemia (IPSS-R intermediate, high or very high)
  - supportive care
  - consider stem cell transplantation according to patient factors (age, frailty, overall health)
  - epigenetic therapy: DNA methyltransferase inhibitors (e.g. 5-azacytidine), histone deacetylase inhibitors

Prognosis
- Revised International Prognostic Scoring System (IPSS-R) uses 5 factors to estimate mean survival:
  - cytology, % bone marrow blasts, hemoglobin, platelets, and absolute neutrophil count
  - based on the calculated score, a patient’s MDS prognostic risk is “Very Low”, “Low”, “Intermediate”, “High”, or “Very High” with a mean survival of 8.7, 5.3, 3.0, 1.6, and 0.8 yr, respectively

Myeloproliferative Neoplasms

Definition
- clonal myeloid stem cell abnormalities leading to overproduction of one or more cell lines (leading to abnormalities in erythrocytes, platelets, and other cells of myeloid lineage)

Epidemiology
- mainly middle-aged and older patients (peak 60-80 yr)

Prognosis
- may develop marrow fibrosis with time
- all disorders may progress to AML

CML = chronic myeloid leukemia; ET = essential thrombocytopenia; IMF = idiopathic myelofibrosis; PV = polycythemia vera; CALR = Calreticulin

Chronic Myeloid Leukemia

Definition
- myeloproliferative disorder characterized by increased proliferation of the granulocytic cell line without the loss of their capacity to differentiate

Epidemiology
- occurs in any age group (mostly middle age to elderly) with a median age of 65 yr

Pathophysiology
- Philadelphia chromosome (Ph)
  - translocation between chromosomes 9 and 22
  - the c-Ab1 proto-oncogene is translocated from chromosome 9 to “breakpoint cluster region” (BCR) of chromosome 22 to produce BCR-Ab1 fusion gene, an constitutively active tyrosine kinase
Clinical Features

- 3 clinical phases
  - chronic phase: 85% diagnosed here
    - few blasts (<10%) in peripheral film
    - ± slightly elevated eosinophils and basophils
    - no significant symptoms
  - accelerated phase: impaired neutrophil differentiation
    - circulating blasts (10-19%) with increasing peripheral basophils (pruritus)
    - CBC: thrombocytopenia <100 x 10⁹/L
    - cytogenetic evidence of clonal evolution
    - worsening constitutional symptoms and splenomegaly (extramedullary hematopoiesis)
  - blast crisis: more aggressive course, blasts fail to differentiate
    - blasts (>20%) in peripheral blood or bone marrow; reflective of acute leukemia (1/3 ALL, 2/3 AML)

- clinical feature
  - 20-50% of patients are asymptomatic when diagnosed (incidental lab finding)
  - nonspecific symptoms
    - fatigue, weight loss, malaise, excessive sweating, fever
  - secondary to splenic involvement
    - early satiety, LQ pain/fullness, shoulder tip pain (referred)
    - splenomegaly (most common physical finding)
  - anemia
  - bleeding: secondary to platelet dysfunction
  - pruritus, PUD: secondary to increased blood histamine
  - leukostasis, priapism, encephalopathy (rare): secondary to very elevated WBC (rare)

Investigations

- elevated WBC, decreased/normal RBC, increased/decreased platelets, increased basophils
- WBC differential shows a bimodal distribution, with predominance of myelocytes and neutrophils
- peripheral blood film
  - leucoerythroblastic picture (immature red cells and granulocytes present, e.g. myelocytes and normoblasts)
  - presence of different mid-stage progenitor cells differentiates it from AML
- bone marrow
  - myeloid hyperplasia with left shift, increased megakaryocytes, mild fibrosis
  - molecular and cytogenetic studies of bone marrow or peripheral blood for Philadelphia chromosome
  - abdominal imaging for spleen size

Treatment

- prophylactic: allopurinol
- chronic phase
  - imatinib mesylate inhibits proliferation and induces apoptosis by inhibiting tyrosine kinase activity in cells positive for bcr-abl. 2nd/ 3rd generation can be trialed based on patient co-morbidities as first line.
  - if loss of response or intolerance (~40%), trial of 2nd or 3rd generation tyrosine kinase inhibitors (TKIs): dasatinib, nilotinib, or bosutinib. Note: Ponatinib only provided for the T315I mutation.
  - interferon-α: may improve response to tyrosine kinase inhibitors; typically now only used for pregnant patients
  - hydroxyurea in palliative setting to reduce WBC
- accelerated phase or blast phase
  - for imatinib-naive patients, use imatinib
  - refer for clinical trial or 2nd/3rd generation TKI and prepare for allogeneic stem cell transplant patients, in blast phase typically get standard AML induction
  - stem cell transplantation may be curative: to be considered in young patients who do not meet therapeutic milestones
  - treatment success is monitored based on therapeutic milestones
    - hematologic: improved WBC and platelet counts, reduced basophils
    - cytogenetic: undetectable Philadelphia-chromosome in the bone marrow
    - molecular: reduction/absence of bcr-abl transcripts in periphery and marrow

Prognosis

- survival dependent on response
  - those achieving complete cytogenetic response (CCR) on imatinib by 18 mo of therapy: 6 yr overall survival >90%
  - those who do NOT achieve CCR on imatinib: 6 yr overall survival of 66%
- acute phase (blast crisis - usually within 3-5 yr)
  - 2/3 acute phase CML have cellular features similar to AML
  - unresponsive to remission induction
  - 1/3 acute phase CML have cellular features similar to ALL
  - remission induction (return to chronic phase) achievable

**Chronic Myeloproliferative Neoplasias: Six Year Follow-Up of Patients Receiving Imatinib for the First-Line Treatment of CML**

Leukemia 2009;23:1054-1061

**Study:** The Randomized Study of Interferon vs. STI571 (IRIS) trial enrolled patients with chronic phase chronic myeloid leukemia (CML-CP) to either imatinib (n=533) or interferon-α (IFN-α) plus cytarabine (n=553).

**Results:** Assessing the imatinib arm specifically at the sixth year point, there were no reports of disease progression to accelerated phase (AP) or blast crisis (BC), toxicity profile was unchanged, and cytogenetic response rate was 82%. Estimated event-free survival was 83% and rate of freedom from progression to AP and BC was 93%.

**Conclusion:** This 6-year update of IRIS demonstrates the efficacy and safety of imatinib as first-line therapy for CML patients.

Detection of the bcr-abl fusion gene is a diagnostic test for CML (present in over 90% of patients)
Polycythemia Vera

Definition
- stem cell disorder characterized by elevated RBC mass (erythrocytosis) ± increased white cell and platelet production
- diagnosis (WHO 2016) requires meeting either all 3 major criteria, or the first 2 major criteria and the minor criterion
  - Major Criteria
    1. hemoglobin >165 g/L in men, >160 g/L in women, OR Hct >49% in men or >48% in women, OR increased red cell mass (>25% above mean normal predicted value)
    2. bone marrow biopsy showing hypercellularity for age with trilineage growth (panmyelosis) with prominent erythroid, granulocytic, and megakaryocytic proliferation
    3. presence of JAK2 V617F or JAK2 exon 12 mutation
  - Minor Criterion
    1. serum erythropoietin level below reference range for normal (must have at least two major criteria if using erythropoetin level)

Clinical Features
- symptoms are secondary to high red cell mass and hyperviscosity (see Erythrocytosis, H6)
- thrombotic complications: DVT, PE, Budd-Chiari (hepatic vein thrombosis), portal vein thrombosis, thrombophlebitis, increased incidence of stroke, and MI
  - due to increased blood viscosity, increased platelet number and/or activity
  - bleeding complications: epistaxis, gingival bleeding, ecchymoses, and GI bleeding
  - if high platelet counts: associated with acquired vWD
- erythromelalgia (burning pain in hands and feet and erythema of the skin)
  - associated with platelets >400 x 10⁹/L
  - pathognomonic microvascular thrombotic complication in PV and ET
- pruritus, especially after warm bath or shower (40%) due to cutaneous mast cell degranulation and histamine release
- epigastric distress, PUD
  - due to increased histamine from tissue basophils, alterations in gastric mucosal blood flow due to increased blood viscosity
  - gout (hyperuricemia), due to increased cell turnover
- characteristic physical findings
  - plethora (ruddy complexion) of face (70%), palms
  - splenomegaly (70%), hepatomegaly (40%)

Investigations (see Erythrocytosis, H6)
- must rule out secondary polycythemia if high Epo level

Treatment
- phlebotomy to keep hematocrit <45%
- hydroxyurea (prior thrombosis or symptoms, severe coronary artery disease, refractory to phlebotomy)
- low-dose Aspirin® (for antithrombotic prophylaxis, will also treat erythromelalgia)
- allopurinol: as needed
- antithrombines: as needed

Prognosis
- 10-20 yr survival with treatment
- complicated by thrombosis, hemorrhage, leukemic transformation (AML)

Idiopathic Myelofibrosis

Definition
- excessive bone marrow fibrosis leading to marrow failure
- characterized by anemia, extramedullary hematopoiesis, leukoerythroblastosis, teardrop red cells in peripheral blood and hepatosplenomegaly

Epidemiology
- rare, median age at presentation is 65 yr

Pathophysiology
- abnormal myeloid precursor postulated to produce dysplastic megakaryocytes that secrete fibroblast growth factor
  - stimulates fibroblasts and stroma to deposit collagen in marrow
- increasing fibrosis causes early release of hematopoietic precursors leading to:
  - leukoerythroblastic blood film (primitive RBCs and WBCs present in blood)
  - migration of precursors to other sites: extramedullary hematopoiesis (leading to hepatosplenomegaly)

Clinical Features
- anemia (severe fatigue is most common presenting complaint, pallor on exam in >60%)
- weight loss, fever, night sweats → secondary to hypermetabolic state
- splenomegaly (90%) → secondary to extramedullary hematopoiesis; may cause early satiety
- hepatomegaly (70%) → may get portal hypertension
- bone and joint pain → secondary to osteosclerosis, gout
- signs of extramedullary hematopoiesis (depends on organ involved)

Myelofibrosis can be either primary (idiopathic) or occur as a transformation of an antecedent PV or ET

A "leukoerythroblastic" blood film (RBC and granulocyte precursors) implies bone marrow infiltration with malignancy (e.g. leukemias, solid tumour metastases) or fibrosis (e.g. IMF)
